The United States public health service thinks the danger great enough to warrant it in calling on the public to kill off the rats. The Illinois Board of Health reprints the public health service bulletin and the Chicago health department is launching an anti-rat campaign.

Rats are important from the public health standpoint because they spread bubonic plague, catarrhal jaundice, and rat bite fever, intestinal parasites, and Trichina. They are important from the economic standpoint because of the enormous amount of food they eat.

The average cat or dog is not a success in preventing rat infestation. The use of poisons at best is haphazard and uncertain. A preparation of arsenous acid, 10 per cent, with cheese meal, meat, or grain, is the most popular poison. The prerequisite of successful trapping is that no food other than the bait shall be available.

The only effective procedure is rat proofing of buildings. It does no good for one man to kill the rats on his place unless his neighbors kill theirs. A rat has been known to travel one mile in two days and several times rats have traveled two or three miles in two weeks. The British Indian rat commission confirms the opinion that halfway anti-rat measures accomplish nothing.

A PERSONAL HYGIENE DEMONSTRATION

By M. EDGAR ROSE, M.D., Director, Division of Child Hygiene, New York State Department of Health, Albany, N. Y.

HEALTH protection, as it should at the present time and will in the immediate future be conceived of, comprises essentially the health education and supervision of every individual from conception to dissolution. In its broadest sense this includes, in addition to the control and regulation of the environment, animate and inanimate, such instruction and continuous supervision as will, within natural limitations result in the bringing of all pregnancies to safe completion; the birth of all children and their growth and development free from defect, disease, or disability; the preventing or at least the delaying of the degenerative changes of adult life; and the discovery and proper treatment at the very earliest possible moment of disease, defect, disability or degenerative change so as to produce the largest possible number of individuals each of whom shall have the greatest possible healthful and useful longevity. This is the ideal which must be striven for. It is obvious that the coincident perfecting of social relations and economic and industrial conditions is a *sine qua non*.

A Measure of Results

The results of the modern health movement which began with the sanitation of the environment and followed with the control of community infection have been striking; the extension and constant and progressive improvement in the carrying out of the now well established methods and procedures, which there is every reason to anticipate, will undoubtedly eventuate in the practical elimination of those diseases which depend essentially upon adverse environment.

The third, and what will most probably be the final stage in the evolution of the health protection movement, namely, that of personal hygiene, has now been entered upon. The campaign for the control of tuberculosis, while concerning itself primarily with the control of community infection, has necessarily and properly entered to a considerable extent into the field of personal hygiene; the campaign for the reduction of infant mortality, now extended to include the broader field of child hygiene, while coming into more or less intimate contact with questions of infectious disease, has been the first to concern itself predominantly with personal hygiene. With the exception of limited efforts by special groups such as the military services, life insurance companies, the Life Extension Institute, and some commercial and industrial organizations, the hygiene of adult life has been untouched.

The need for intensive work to cover the entire field of personal hygiene, a need which has always existed, has not been at all realized in the past and is today but very partially, vaguely, and indifferently appreciated by the general public. While the more enlightened public health workers have grasped the full significance of the importance of such efforts, for a number of well known reasons they have been unable to meet the need in any but a very superficial manner, except in certain communities and with regard to certain special phases. It may be of interest briefly to indicate some of the most salient features of this need, and for this reason the following is submitted. Mortality and morbidity statistics, believed to be sufficient to indicate what the more complete records show as substantiating the following general statements, are hereto appended.

In the United States as well as in the other civilized countries of the world, the general death rate has been falling steadily for a number of years. An analysis of specific death rates will reveal the fact, however, that this decline has been most pronounced in the younger age groups, *i. e.*, in infancy, childhood, and early adult life, and particularly in the group of communicable diseases which affect more especially the younger members of the community. In middle and later adult life there has been an appreciable increase in mortality, the degenerative changes affecting the circulatory and renal systems, and cancer are now taking a larger toll at earlier ages—a condition which obtains in few of the European countries; it is notably absent in England, Wales, and the more im-

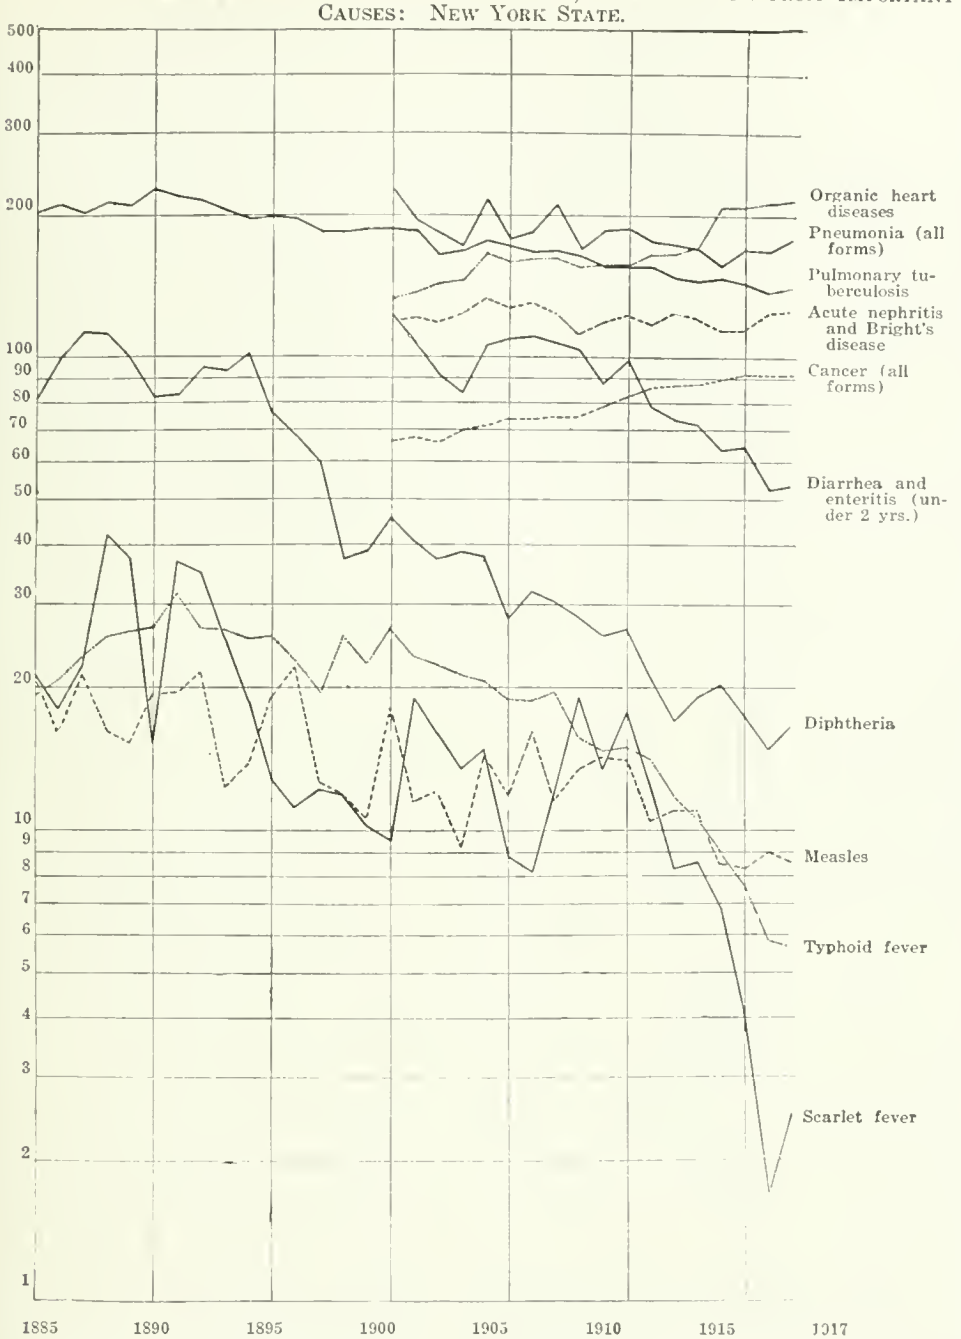
TABLE III.—Movement of Death Rates per 100,000 Population from Important Causes: New York State.



This chart is so constructed that equal vertical distances represent equal *ratios* rather than equal absolute differences. Curves changing at the same *rate* are parallel; of two curves changing at different *rates*, the one with the greater *rate of change* is steeper.

portant of the north continental group, and the result in this country is an index of the character and intensity of the efforts heretofore made.

Statistics Are Fragmentary

While mortality statistics are sufficiently complete and accurate, for obvious reasons those relating to morbidity are as yet very fragmentary. Aside from what is shown by clinical experience and records, by figures obtained through examinations such as those of life insurance groups, or of school children, and those of the military services—notably for the recent draft—estimates must be relied upon as indicating what is generally accepted as being true, namely, the fact that very few individuals of any age group are free from preventable or remediable disease, defect, or disability and that the span of really healthful and useful life is far shorter than it should be.

The causes for the above mentioned conditions with regard to mortality and morbidity in our population are essentially ignorance, neglect, and those factors often referred to as the stress and strain of life, the latter including vicious habits and unfavorable social, economic, and industrial conditions. The remedy is obvious. The methods and procedures which should be followed have been sufficiently developed and the results obtained of a character so satisfactory as to warrant a continuance and an extension along the lines laid down. The only logical plan, in theory, would be one comprehensive enough to include all members of the community, and this should prove successful in practice. In view of the fact that child hygiene activities are concerned with the mother and children, it should be feasible and much more economical to include also the father and other adult members of the household. As to what agencies should undertake and carry on this work there can be no question when the matter is viewed in the broad light which it merits. The public as a whole, being the great loser and potentially the great gainer, should carry it on as it does cultural education. Up to the present, as previously indicated, the major portion of health protection activities with which public health authorities have concerned themselves have, for well known and proper reasons, been more especially the performance of duties and the exercise of powers in connection with the sanitation of the environment and the control of community infections—activities commonly recognized as being of a police character. While excellent work is being done and good results secured in the field of child hygiene, that only a beginning has been made will be better appreciated when the statement is offered that in New Zealand the infant mortality rate has been reduced to below 50, due to a well thought out and efficiently executed plan of campaign largely the result of private enterprise and financial support. In this country as a whole, and even in New York state, there are

still too few municipalities where the child hygiene activities are being carried on by the public authorities. In so far as adult hygiene is concerned, none of the municipalities has as yet even made a beginning.

Health Demonstration Effectual

Experience in New York state and elsewhere in connection with other lines of public health activity, such as tuberculosis, has shown that, to secure the adoption and efficient and continued execution of any comprehensive efforts, there is no method which can approach in efficiency that of an actual demonstration. It is believed that the conducting of a demonstration in the personal hygiene of childhood and adult life showing the need for and the means of carrying on such work would result in the very prompt adoption of this work by practically all municipalities of the enlightened commonwealths of the Nation.

Such demonstration should be conducted in a city of approximately 75,000 population, be continued for at least three years, and preferably five, and have the hygienic viewpoint rather than the clinical. The need for medical and surgical care and treatment should be demonstrated and should be sufficient to stimulate, and if adequate provision is not already existent, it should be provided by the community. The cooperation and assistance, including that of a financial character, of all local organizations, should be enlisted and retained. The cooperation and aid of the state health department is essential. It should be understood that what is here recommended has no connection with state medicine, health insurance, or any of the other similar measures now being widely considered. The scope and character of the activities which should be undertaken may be briefly outlined as follows:

I.—Education and instruction of the general public and of special groups in the problems presented by mortality and morbidity and their solution, in order to arouse the necessary interest and secure the support and cooperation so essential to the success of any such undertaking.

II.—Instruction in physiology and personal hygiene should be (1) compulsory in public schools, but (2) voluntary for all adults.

III.—Specific instruction and supervision by physicians

and public health nurses at home and at health centers.

(1) *Maternity* care to include:

(a) Hygiene of pregnancy and of early infancy: (i) Through at least monthly visits throughout pregnancy to health center until end of sixth month and every two weeks thereafter; (ii) literature to be given mother to acquaint her with principles of hygiene of pregnancy and of early infancy.

(b) Puerperium: (i) Daily visits through the fifth day and at least two other visits during the second week by physician or nurse.

(c) Continuous health supervision from birth for every infant.

(2) *Infancy and pre-school period* would require instruction, with demonstrations, to mothers in the care and feeding of children at least once a month throughout the first year and at regular intervals throughout pre-school period.

(a) Instruction to mothers at home would present the (i) value of breast feeding; (ii) technic of nursing; (iii) technic of bath, sleep, clothing, ventilation, and general care of baby; (iv) preparation and technic of artificial feeding; (v) dietary essentials and selection of food for infant and for older children; and (vi) prevention of disease in children.

(3) *School children* should be supervised as to:

(a) Personal hygiene and diet, and (b) home visits planned to advise and instruct mothers in

TABLE VIII.—Pre-School Period. Results of Physical Examinations at New York City Baby Health Stations, of Children of Pre-School Period.

Defects found	Number	Per cent
Defective teeth	780	34.5
Defective nutrition	550	24.6
Hypertrophic tonsils	550	24.6
Defective nasal breathing.....	528	23.
Orthopedic defects	184	8.2
Defective vision	84	3.7
Pulmonary diseases	57	2.5
Cardiac disease	40	1.8
Nervous disorders	31	1.6
Defective hearing (428 children not examined for this)	29	1.6
Total examined	2,228	100.
Total found with general defects.	1,295	58.1
Total found with defects of teeth only	287	12.8
Total defective children	1,582	71.0

*Prepared from New York City Health Department Bulletin.

TABLE IX.—School Children (Estimates of Dr. Thos. D. Wood) 22,000,000 School Children in United States.

(1)	At least 1%, or 200,000 mentally defective.
(2)	Over 1%, or 250,000 at least—organic heart disease.
(3)	At least 5%, or 1,000,000 have now or have had tuberculosis.
(4)	Five per cent., or 1,000,000—defective hearing unrecognized—gives many reputation of being mentally defective.
(5)	Twenty-five per cent, or 5,000,000—defective eyes.
(6)	Twenty per cent. at least, malnutrition.
(7)	From 15 to 25%, 3,000,000 to 5,000,000—adenoids, diseased tonsils or other glandular defects.
(8)	From 10 to 20% or from 2,000,000 to 4,000,000 have weak foot arches, weak spines or other joint defects.
(9)	From 50 to 75% or from 11,000,000 to 16,000,000 have defective teeth.

principles of hygiene, nutrition, and the selection of family diet.

(4) *Adolescents* require to receive:
- (a) Ample diet and special attention to growth-producing foods;
- (b) Sufficient sleep, rest, and fresh air;
- (c) Adequate and suitable clothing;
- (d) Recreation and proper exercise for physical development; and
- (e) Knowledge of sex hygiene and reproduction.

(5) *Adults* need adequate care to insure:
- (a) Proper diet;
- (b) Sufficient sleep, rest, and fresh air;
- (c) Adequate and suitable clothing;
- (d) Recreation and exercise;
- (e) Suitable occupation and prevention of occupational strain and poisoning; and the
- (f) Correction of vicious habits.

IV.—Periodic examinations by physicians should include:

(1) Maternity cases, covering:
- (a) Complete physical examination as early in pregnancy as possible, including examination of heart, lungs, abdomen, and urine and the taking of blood pressure.
- (b) Internal examination and pelvic measurements before seventh month in primipara.
- (c) Examination of urine every four weeks during early months, at least every two weeks after sixth month, and more frequently if indicated.
- (d) Wassermann test, when indicated.
- (e) Examination before discharging patient from observation, at a date not later than six weeks after delivery.

TABLE X.—Analysis of Physical Causes for Rejection for Service in the U. S. Navy and Marine Corps, 1916, as Given in Report of the Surgeon General of the Navy.

		Per cent
Number of men examined	82,592	
Number of men rejected for all causes	51,167	62
Causes of rejection:		
Eye	9,452	11.4
Underweight	5,397	6.5
Flatfoot	5,028	6.08
Defective teeth	4,878	5.9
Deformities	3,533	4.3
Varicocele or varicose veins	3,105	3.8
Heart affections	2,302	2.8
Height, under	2,124	2.6
Poor physique	1,633	2.0
Ear	1,376	1.7
Genito-urinary venereal	1,347	1.6
Hernia or tendency to	1,312	1.6
Skin disease	1,094	1.3
Pyorrhoea	896	1.08
Height and weight, under	921	1.1
Tuberculosis or suspects	909	1.1
Tonsillar conditions	588	.72
Genito-urinary, non-venereal	548	.66
Nasal abnormalities	476	.67
Febrile conditions	381	.46
Mental disorders	302	.36
Goiter or tendency to	294	.35
Defective speech	132	.15
Miscellaneous causes	2,820	3.41

(2) *All infants and pre-school children* should receive periodic examination and weighing and measuring, which should be under the supervision of a physician.

(3) *For school children* there should be:
- (a) Complete standardized basic physical examination once a year;
- (b) Determination of weight and height at beginning and at end of year;
- (c) Monthly weighing;

TABLE XI.—Analysis of Typical Industrial, Commercial, and Insurance Groups (Figures Derived from More Than 10,000 Cases) (Fisher and Fisk).

	Men av. age 34 Per cent	Women av. age 25 Per cent	Men av. age 26 Per cent	Women av. age 26 Per cent	Life insurance av. age 37 Per cent
No physical impairment reported: no modification of living habits required	0	0	0	0	0
Slight physical impairment or defect requiring observation or hygienic guidance	10	23	10	12	6
Moderate physical impairment or defect requiring some form of hygienic guidance or minor medical, dental or surgical treatment	41	54	52	58	63
Moderate physical impairment or defect, medical supervision or treatment advised in addition to hygienic guidance	35	19	27	21	21
Advanced physical impairment or defect requiring systematic medical supervision or treatment	9	4	9	9	7
Serious physical impairment or defect urgently demanding immediate attention	5	0	2	0	3

- (d) Special medical examinations of children referred by teacher or nurse; and
- (e) Examination by psychiatrist of all atypical or retarded children.

(4) *Adolescents* should have complete standardized basic physical examination, including weight and height, at least once a year.

(5) *Adults* should be subjected to:
- (a) Complete standardized basic physical examination at least annually, preferably semi-annually, including blood pressure determinations and, when indicated, Wassermann tests, x-ray, and other special diagnostic procedures; and (b) urinalysis quarterly.

V.—Hygienic and corrective treatment should be recommended.

VI.—Follow-up work should be undertaken by nurses to see that all such recommendations are carried out, and

VII.—Health records should be kept for every individual throughout life.

Proper Care and Treatment

VIII.—The corrective measures and agencies should be as follows:

(1) General and special hospitals; dispensaries and clinics for maternity cases, children, etc., and for tuberculosis, venereal diseases, dental, eye, ear, nose, throat, skin, and orthopedic clinics would be required.

(2) Open air clinics and rest periods would need to be provided for pre-tuberculous and certain tuberculous children and children with grave malnutrition.

(3) Special classes for children needing some form of special instruction due to physical or mental defect.

(4) Nutrition classes for physically sub-normal chil-

dren, to include (a) maintenance of mid-morning lunch or hot noonday meal when necessary.

It is to be understood that the above is intended for the entire population. A certain proportion of this, approximately between 40 and 50 per cent, should, and as the result of education most probably will, utilize private agencies such as physicians, nurses, etc. For the remainder of the population it will be necessary to provide an organization, which for a city of 75,000 population should as a minimum be as follows:

In such a community there would be about sixteen thousand families, with approximately 4.6 persons per family; in the case of the groups whose social and economic status is such that they either cannot or will not avail themselves of private physicians, this figure is considerably larger. The number of pregnancies can be estimated as between one thousand eight hundred and two thousand; of children under two years of age, at 3,000; from two to five years, inclusive, at 4,000; of school age—five to sixteen years—at 14,000; and of adolescents and adults, at 52,000.

I.—The central organization should include in its personnel:		
(1) A director (physician)	$5,000	
(2) A supervising nurse	2,500	
(3) A supervisor of social work	2,500	
(4) An office force:		
(a) Secretary-stenographer	1,200	
(b) Two clerks at $1,000	2,000	
		$ 13,200
II.—The field organization would follow the health center plan and would require three unit districts, one to each 25,000 population.		
(1) Health center superintendent (nurse)	$ 1,800	
(2) Nursing staff of eight, at $1,200 each (One to each 75-80 families)	9,600	
(3) Social service staff of three, at $1,200 each (One to each 300 families)	3,600	
(4) Instructor in food and nutrition	1,800	
	$16,800	
Three units at $16,800		50,400
III.—All three centers would be served by the medical staff:		
(a) Obstetrician on full time to handle fifty patients a day, one monthly visit per patient	$ 3,000	
(b) Physicians—eight on full time, at $3,000	24,000	
		27,000
Children from 0-2 would run 60 patients a day per physician, and children from 2-5, 54 patients a day per physician. Adolescents and adults would number 20 to 25 patients a day per physician.		
IV.—The school children would be supervised by a unit for each school, as follows:		
(1) Physicians, three on full time, service at the schools, at $3,000 each	$ 9,000	
(2) Nurses (service at the schools), six, at $1,200	7,200	
(3) Instructors in food and nutrition—two for all the schools at $1,800, one day a week in each school	3,600	
(4) supervisor and director for tests for vision and hearing	600	
(5) Attendance officer, a trained nurse, as 75 per cent of absence is due to illness	1,200	
		21,600
V.—Laboratory service	$ 2,500	
VI.—Initial equipment, supplies, miscellaneous expenses, and contingent fund	5,300	
		$120,000

VII.—Volunteers may be employed for such work as clerical, etc., which may be needed.

Utilize Present Facilities

It is to be understood that in many of the municipalities of this size, as, for example, in any of the second class cities of New York state, there are at present available some of the facilities, such as school physicians and public health nurses. These should be utilized as part of the organization outlined.

For special diagnostic examinations and consultation services the facilities of the local hospitals and their staffs should be employed. These institutions should also provide additional nursing service, thus affording an excellent opportunity to give practical instruction in public health work to their pupil nurses.

Quarters and their upkeep should be provided by the community. Clinical care and treatment should be supplied by the hospitals, dispensaries, and clinics. If these prove to be insufficient, no better means for securing the necessary additions could be had than the actual demonstration of such needs. The treatment of communicable disease, being properly the function of the health authorities, should be provided accordingly.

Dental service has not been included in this outline, as it is essentially therapeutic and should be provided in the same manner as is other treatment. The physicians of the organization should be qualified to discover the need for such care and treatment. The necessary social readjustments should be looked after by the social workers of the organization, who should discover any need for economic relief and refer same to the proper charitable organizations. Where remediable unfavorable industrial conditions obtain, this should prove the most efficient means for securing the necessary corrective changes.

After the selection of the municipality in which the demonstration is to be conducted, which choice should depend upon the assistance—financial and otherwise—and cooperation promised, a detailed survey of specific needs and existing agencies should be made as the first step.

Such demonstration requiring the expenditure of substantial sums of money, can of necessity be financed only by some private organization concerned with public health matters. However, careful consideration of the entire project, viewed from every standpoint, leads to the conclusion that, if possible, it would be highly desirable and advisable to secure some of the funds needed from local sources, either through municipal appropriations, private subscriptions, or both. Perhaps at present the bulk of such local financial assistance would be procurable only from local private sources. As a suggestion it is submitted that about one-third of the total of $120,000 *per annum* needed, or $40,000, be so provided, the remaining two thirds, $80,000, to be donated by the outside organization. The history of similar ventures has been such, as a rule, that when the need for and value of the work being demonstrated and privately financed has been shown, no difficulty was encountered in having the municipality assume the entire burden. There is no reason to anticipate that in this case the same result will not ensue. As to the feasibility of any of the municipalities assuming such burden, the following is offered: There are now seven cities of the second class—50,000 to 175,000 in population—in the state of New York, with an average population of 102,727. The *per capita* appropriation for police, fire, and health protection averages for each of the seven cities 2.54, 2.51, and 0.65, respectively. The individual figures as of July, 1919, for the several cities are as follows:

	Syracuse	Albany	Yonkers	Schenectady	Utica	Troy	Binghampton
Police	2 66	2.75	3.32	1.66	1.80	2 45	2.08
Fire	2 82	2.96	2.21	1.54	2.62	1 96	2.50
Health	.68	.42	.79	.51	.43	.23	.36

If, for example, Utica or Troy would take on this work at the rate of $125,000 annually in addition to what either at present spends, the total per capita for health protection would be but $1.90 in the case of Utica (10 cents per capita more than it now spends for police protection and 72 cents less than for fire protection); and in the case of Troy $1.89 per capita (56 cents less than is now spent for police and 7 cents less than for fire protection).

The Span of Life Increased

In conclusion, it is submitted that not only can and should the mortality be reduced, but to even a greater degree the morbidity; not only the mere span of life increased but, what is of far greater importance, the useful and healthful portion thereof extended. The method for most effectively attacking the problem of the prevention and early remedying of disease, defect, and disability beyond the reach of measures aimed at the control and regulation of the environment has been indicated; its efficient execution would bring such results as to make the expenditure of effort and finances negligible. It is believed that the demonstration recommended would prove to be one of the most notable achievements in the modern health protection movement.

CRIPPLES IN NEW YORK CITY

THERE are in New York City about thirty-six thousand cripples, according to the findings of a survey recently made. The survey was inaugurated by the representatives of forty-one organizations, associations and hospitals engaged in work for cripples, at a conference which was the result of the efforts of the New York Committee on After Care of Infantile Paralysis Cases. The expenses were met by contributions from certain of these agencies and a liberal gift from the Rockefeller Foundation.

The responsibility for the after care of the survivors of the 1916 infantile paralysis epidemic in New York City has since that time been vested in the above named Committee, representing all the agencies interested in these children. This Committee provided a system of follow-up, including necessary financing, transportation, and home care, which proved so beneficial in its results on the thousands of cases recorded that the Committee early in 1919 resolved to find whether all the city's needy cripples were being cared for and, if not, the extent of the unmet need.

The survey was made under the direction of Mr. Henry C. Wright, of the Hospital and Institutional Bureau of Consultation. The aim was to ascertain the number of persons crippled in New York by different causes, and the nature of care and treatment that is being given to them, with the chief emphasis on the causes which produce cripples. Instead of surveying the entire city, which would have been a very large task, six typical districts, having an aggregate population of 110,000 people, were selected. In these districts a house-to-house canvass was made. When cripples found had not been diagnosed at a recognized clinic or hospital, an orthopedic surgeon was sent to the home to make a full diagnosis. The statistics of causes and classifications thus obtained are reasonably accurate. In addition to the field canvass, the work of all organizations, hospitals, and institutions dealing with cripples was examined to determine its character and scope. The full report has been published in book form and distributed widely by the New York Committee on After Care of Infantile Paralysis Cases.

The Report defines a cripple as "one handicapped by some limited or distorted use of muscles, joints or skeletal members." This was interpreted to exclude the blind, the aged, and the mentally defective. Children with rickets were included only when the disease took the form of obvious physical deformity. Flat feet were not included, inasmuch as flat foot seldom is much of a hindrance to earning a livelihood. The Report confirms previous knowledge that crippling conditions arise chiefly during childhood. It found that of those crippled after the age of 15, 61 per cent were crippled by amputations or traumatic conditions, whereas these causes produced less than 8 per cent of the cripples under the age of 16; and during this childhood period 65 per cent of the crippling conditions were due to poliomyelitis and congenital conditions, if rickets be excluded.

The inference is drawn from the investigation that bone tuberculosis is on the decrease. Of the cases found, 88 per cent were children under fifteen years of age.

An interesting comparison is made between the incidence of bone tuberculosis found in New York City and in Birmingham, England. Among children the incidence in New York City showed a percentage of but 6.4, while in Birmingham it was 39.5 per cent. Infantile paralysis was the cause of crippled condition in 44 per cent of the cases of children, which corresponds very closely to the 41 per cent found in Cleveland during a corresponding survey in 1915-1916. Inasmuch as the survey in New York City was made subsequent to the epidemic of 1916, and the survey in Cleveland previous to that epidemic, the close correspondence of these two percentages would give some ground for inferring that the incidence of poliomyelitis during a period of years is fairly constant, irrespective of an occasional epidemic.

A competent orthopedic surgeon passed upon all cases in their homes that had not been disagnosed by some recognized clinic or hospital. On the basis of his findings it is estimated that there are in the city fully one thousand cases of bone tuberculosis, Potts' disease, and poliomyelitis not having been diagnosed or treated. Of the cases not previously diagnosed, about 25 per cent showed a good prognosis; about 20 per cent, prognosis good provided braces or appliances were supplied and used.

It was found that a large number of cases cease to go to clinics after treatment has been begun. It was estimated by the survey that fully 3,700 cases in New York City afflicted with one of the three before mentioned diseases, having started treatment in clinics, had not been attending for six months. These neglected cases call for closer central registration and supervision.

The Report in substance states that a comparatively small number of operative beds are needed, provided there be a sufficient number of convalescing beds; that clinical facilities need not be so large if combined with home treatment; that transportation requirements will be correspondingly small if home treatment is used; that the services of the surgeon will be called for very little in connection with infantile paralysis cases, provided proper care is given to the case during the acute stage of the disease. As a result of such care, almost no deformities resulted to children during the epidemic of 1916.

INDIANS AND HEALTH

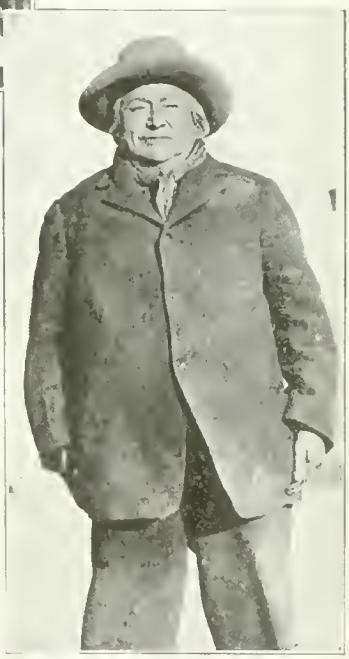
Times have certainly changed. It wasn't many years ago that when a crowd of Sioux Indians got together of an afternoon there was usually a considerable amount of battle, murder, and sudden death in the air. According to the story books, the proceedings usually opened with firewater and scalpings, and closed with an entertainment in which a paleface, tied to a stake, was the chief performer.

But nowadays things are different. When the Sioux Indians in Minnesota get together it is to listen to public health lectures delivered in their own language, and frequently by members of their own tribe. There is a great deal of tuberculosis among these Indians, and the American Red Cross is endeavoring by means of these lectures to educate them in preventive measures against the disease. The old chief, Two Hawks, is an eloquent lecturer for the Red Cross. And a certain squaw, who had never before appeared in public, prefaced her remarks with the statement that if her audience were not composed of ladies and gentlemen she wouldn't talk to them.

A hundred years ago it would have been a brave paleface who would have delivered a lecture to an audience of Sioux. Some such lectures were delivered, but they were usually in the nature of deathbed remarks. Today, however, the Indians look upon these things differently, and they are eager to learn all the good that the Red Cross can teach them. The Indians are now self-organized for health work and they are concerned with their own hygienic problems as well as interested in relief work for refugees overseas.

Indian Members of the Browning, Mont., Red Cross Chapter who helped in the knitting of sweaters and scarfs for soldiers and refugees overseas. The Indians shown are the following: 1, Mrs. Sarah D. Wilbur, Field Matron (an Indian); 2, Mrs. Medicine Owl; 3, Mrs. Last Star; 4, Mrs. Louise Chanepine; 5, Wades in the Water; 6, Julia Wades in the Water; 7, Wolf Tail; 8, Mrs. Wolf Tail; 9, Mrs. Bull Calf; 10, Mrs. Mary Powell. (Photographed by the American Red Cross.)

"Wades in the Water" is a member of the Indian police and an active worker in the Red Cross chapter at Browning, Mont. (American Red Cross.)



Wolf Tail is a full-blooded Blackfoot Indian, member of the Browning, Mont., Red Cross chapter, who is the largest Indian donor to the American Red Cross War Fund.

MISSISSIPPI VALLEY CONFERENCE ON TUBERCULOSIS

The Mississippi Valley Conference on Tuberculosis, which convened in its eighth session at Duluth on September 2-4, 1920, brought together a body of workers whose discussions on the supervision of the tuberculosis, on open air schools, modern health crusades, industrial hygiene, and the organization of tuberculosis clinics dis close the scientific basis of present day tuberculosis work.

NEW YORK STUDIES MALIGNANT DISEASE

The Legislature of the State of New York at its last session appropriated $250,000 to purchase two and one-quarter grams of radium for the use of the people of the State of New York. One gram of radium, valued at $120,000, was recently delivered by the Bureau of Standards at Washington to representatives of the State of New York for the State Institute for the Study of Malignant Diseases at Buffalo for use in cancer research. The radium was given a scientific test by the Bureau of Standards before its delivery.

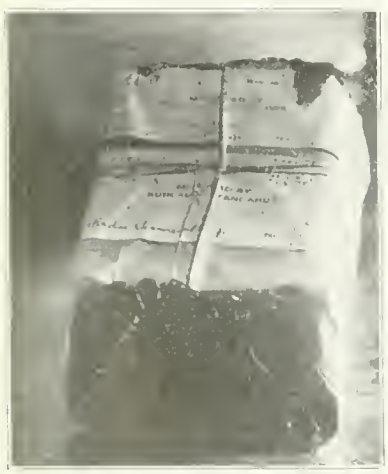
Underwood & Underwood.

The formal transfer of one gram of radium to officials of the State Institute for the Study of Malignant Disease, New York City.

The purchase of radium by the state is the first instance where radium has been acquired by the people for social use. It is the largest amount ever bought at one time, as well as the largest amount ever tested by the Bureau of Standards.

Dr. Harvey R. Gaylord, director of the Institute for the Study of Malignant Diseases, announced that on and after October 15 the Institute would administer radium treatment free of charge. Speaking of the subject in an interview in the *New York Times*, Dr. Gaylord said:

"This first purchase by any state of radium marks an important step in the health activities of the country. For radium is the only therapeutic agent whose cost is beyond even the well-to-do. Of course, radium is in use in the State now, and its value in combatting cancer, especially in its early stages, already has been abundantly demonstrated. There are about seven grams used in New York City, and one or two in the rest of the state. But people must pay for the treatment. After October 15, any doctor may send his patient to us for free treatment by radium. We have enough of the mineral to take care of two million people, and it lasts anywhere from two thousand to thirty-two hundred years. The only limit is our ability to house those who come to Buffalo for treatment. The city will certainly become the radium center of the state."



Underwood & Underwood.

A close up view of the package containing the $120,000 worth of radium recently acquired by the State of New York.

THE AMERICAN PUBLIC HEALTH ASSOCIATION

The spirit and purpose of the health convention at San Francisco September 13-15 are evidence enough of an awakened public consciousness in matters of public welfare, and of the "get together" program of all the specialties to make effectual in physical and racial betterment the improved methods of the laboratory, evaluations that are growing out of analytical study of statistics, and the latest results of sanitary engineering.

The many related topics to public health made up complex and varied symposiums, but general sessions provided means of getting the clear and mutual understanding that makes for intelligent cooperation. The relative functions of official and non-official health agencies were threshed out in general discussion. The technical papers and reports from the Laboratory Section tend still further to standardize analytical procedures. The Health Administration Section offered a highly interesting symposium on narcotic drug control. Special programs were arranged on Child Hygiene.

The industrial hygiene program as arranged by Professor Winslow offered a program of the most definite help to the industrial physician, the symposium on industrial health education being held jointly with the Sociological Section. The topics included: Labor camp sanitation as a basis for education and citizenship; health supervision in industry; industrial health education—a means and an end; and health education in industry, all these discussions being introduced by men authoritative in this field. Other sections presented related subjects, including the results in the home of the workmen of the hygienic principles applied to industry and the hygienic control of hazardous trades.

Special provision was made at this meeting for lectures on personal as well as community hygienic measures, and this work was supplemented with many popular lectures before clubs, school societies, and other organizations.

The officers elected for the coming year are: M. P. Ravenel, M.D., Columbia, Mo., president; T. B. Beatty, M.D., Salt Lake City, state health commissioner of Utah, first vice-president; Louis I. Dublin, M.D., of New York, second vice-president; William C. Hassler, M.D., San Francisco, third vice-president; Roger I. Lee, M.D., Cambridge, Mass., treasurer; A. W. Hedrick, Boston, secretary; Doctors W. S. Rankin, Raleigh, N. C.; C. J. Hastings, Municipal Health Officer of Toronto, and Peter H. Bryce, Ottawa, members of the executive committee.

The following directors were elected: S. J. Crumbine, M.D., Topeka, Kan.; J. A. Ferrell, M.D., of New York; Charles J. Hatfield, M.D., of Philadelphia; M. M. Seymour, M.D., of Regina, Saskatchewan; and Ray Lyman Wilbur, M.D., president of Stanford University. The selection of the next convention city was left to the Executive Committee.

The number of limbs lost in American industry every year is 26,000. This is six times the number of amputations among American soldiers in the year of war. As soon as we have made peace in Europe, can't we do something to prevent the wounding of workmen at home?

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M. OLMSTED, R. N., *Editor*

SAN FRANCISCO MEETING DISCUSSES NURSING

SEVERAL phases of health work of especial interest to nurses formed the subjects of discussion at the sectional meetings of the American Public Health Association in San Francisco. In all efforts to supplant the old conception of public health work as consisting of police power by newer measures whose objective is to carry health practices to the people, the function of the public health nurse becomes more and more important. In addressing the Public Health Administration Section, Charles J. Hastings, M.D., municipal officer of health of Toronto, Ont., emphasized the value of the public health nurse.

Dr. John Dill Robertson's paper, read by Allen J. Hruby, M.D., of Chicago, gave an interesting account of the marshaling of nursing reserves in caring for epidemic diseases. Doctor Robertson's thesis that two months intensive training would enable any woman to render inestimable service in the sick room and afford a nursing contingent for emergent conditions was unquestioned; but, as might have been anticipated, opposition was voiced against any scheme for the training of nurses which would tend to lower the standards of educational requirements or would in any way serve to place upon the persons trained under such régime the same responsibilities as those rightly assumed by nurses regularly trained. Nor could approval be expressed for an official sanction which in the public mind would place these short time students in the same category with nurses regularly graduated from accredited schools. Some of the nurses present vigorously argued that these "practical" nurses, unless controlled by legislation on the subject, will demand fees on a par with nurses who have had three years in a hospital. The training assumed in a registered nurse is the technical skill that accrues from oft recurring tasks, the ready common knowledge long since acquired and repeatedly used, and the stability which results from discipline over a long period of time. The broadened scope of the nurse in public health fields calls for higher requirements of training, and any measure which proposes to make up the present shortage by lowering the standards simply begs the question.

The health center plans fostered by the American Red Cross was the subject of the discourse by E. A. Peterson, M.D., director of the health service, Washington, D. C., before the civilian relief section of the American Red Cross. He challenged the Red Cross, with its fourteen million members, to bring to communities all the health knowledge now in the hands of experts and teach the public how to use this knowledge. The health center program, he said, was conceived as the next great step in health work, again bringing to the fore the important function of the nurse for civilian relief.

STUDIES IN NUTRITION

WE PRESENT on another page of this issue a discussion by Miss Jane Teare Dahlman of the fundamental factors in nutrition, a knowledge of which must be considered an essential part of the nurse's training. In her capacity of director of the School of Public Health of the University of Louisville, and of the Bureau of Public Health Education of the Kentucky State Board of Health, Miss Dahlman speaks authoritatively, while her first hand knowledge of nutrition as affecting the public health gives her the proper perspective as to its importance.

The tendency on the part of the popular mind to associate the idea of malnutrition with disease is probably due to recent studies of certain diseases of serious import to the community, which emphasize the fact that their primary cause is to be found in dietetic sources. Rickets, beriberi, pellagra, and scurvy are conceded to be due to specific deficiencies of diet, and it may well be assumed that much of the general ill health attributable to such causes has been often misunderstood and wrongly treated. A striking point in this connection is the ease with which these inefficient diets can be converted into efficient ones, once the facts are arrived at.

But in ascertaining the facts in regard to the dietary, a study of the national supply of foods or even of family budgets gives only partial information. Malnutrition finds its source in ignorant and ill judged feeding, or badly treated and ill chosen foods, as often as it is traceable to poverty. Nor is nutrition to be regarded too exclusively from the standpoint of energy supply without due regard to the accessory substances—vitamines—at least two of which must be present in any dietary providing proper nutrition. On food lacking these, young animals fail to grow and even adult animals sooner or later go to the ground, says Hopkins[1] in reporting some discriminating experiments on dietary management. The question is one of national importance and is especially urgent in connection with the proper feeding of the young. The child who is the victim of malnutrition is smaller in growth, more or less retarded in intelligence, and is much more vulnerable to disease than the normal child.

The whole question of the dietary rightly commands the public interest and calls for special attention from public health nurses. We are yet at the bare beginning of the study. S. P. M.

SCIENTIFIC CONSIDERATIONS IN NUTRITION*

By JANE TEARE DAHLMAN, R.N., Director, School of Public Health, University of Louisville, and of the Bureau of Public Health Education, State Board of Health, Louisville, Ky.

NUTRITION—what does it mean? "Nutrition is the sum of the processes concerned in the growth, maintenance, and repair of the living body as a whole or of its constituent organs," is the definition of Dr. Graham Lusk.

Could anything more vitally concern doctors and nurses, the guardians of the health of men, women, and children? Only within a comparatively few years, though, has this important matter been given scientific consideration. It was recognized that folks wanted to eat, that they must eat to live, that some, in fact, live to eat. But just what they did eat was of comparatively little concern so long as the food was obtainable and, most important of all, palatable.

The Appetite No Guide

There used to be, and there still is, a popular idea prevalent that "appetite is a good guide for the stomach." When that adage was coined, doubtless it was true; but that was in ages when men and women lived natural lives. It does not apply, however, to people of this day and generation because we are not living natural lives, nor have our forbears for generations back lived natural lives. Civilization has brought to us what we call advantages—many of them—but these advantages bring with them a demand, an insistent demand, for numerous changes and adaptations in our artificial mode of living. It is a long jump from the naked or skin-clad, barefoot family living in a brush shack or a skin tent, to the modernly attired family living in the artificially heated house of today. It is a long jump, too, from the roots, herbs, and cracked corn of that earlier diet to what we now serve on our tables or to which we serve ourselves at cafeterias.

To all of these changes in the manner of living our physical bodies have responded in various ways. It is not so long since America was known to the English as the "land of pie and indigestion," while we in America thought of England as the "land of roast beef, plum pudding, and gout." Modern physicians, however, did begin to watch more carefully the diet of their patients. Perhaps the one case that gave most to scientific thought in nutrition was that of Alexis St. Martin, the Canadian whose gunshot side afforded an opportunity for Doctor Beaumont's observation of the digestion of food. Following him, there is a direct line of sincerely interested scientific workers seeking to solve the mysteries of the processes concerned in "the growth, maintenance and repair of the living body as a whole and of its constituent organs." Often, at great personal sacrifice, these scientists have earnestly sought to discover these secrets of life for the masses of people unable themselves, for various reasons, to undertake such studies—outlining, suggesting, and recommending the kinds and amounts of food necessary for the continuation of their bodily processes.

Just as the nutritional expert needs to know physiology and anatomy, so does the health worker need to know nutrition. Nurses and doctors both have said to me: "Oh, I don't know anything about calories. Nutrition is too much for me! Let the dietitians attend to that."

I deny absolutely that anything is too difficult for us if it calls to us as professional health workers. The nutritional needs of the people do call to us professionally and it is our duty to so prepare ourselves that we can answer these calls intelligently and effectually.

What a Calorie Stands For

To learn that a calorie is not such an awesome thing after all, but merely a standard of measure used to designate the heat or energy value of a certain definite quantity of food; that each of the foods has different caloric values; that under various circumstances the human body requires varying numbers of calories; that calories, or definite amounts of foods generating heat and energy, are not all that the living body requires but that protein, water, bulk, vitamines, and mineral salts are all necessary to life; and that at different ages and under diverse living conditions, the required amounts and compositions of the diet vary; are all matters of vital importance.

Here are two things we must know: (1) The nutritive requirement of the body—the actual amount and the kinds of food necessary to promote bodily growth, maintenance, and repair for all ages and conditions of the people we serve; and (2) the nutritive properties of foods—the amounts and kinds of nourishment contained in each food which is available and can be digested and assimilated by the man, woman, or child. It is now possible to measure this requirement with surprising accuracy.

An adequate supply of fuel is necessary to keep any machine going. The fuel for the human body is food. The calorie is taken as the unit of measurement of fuel or heat contained in food. The calorie is no more abstract and difficult to determine than the inch in measuring a yard or the degree in measuring the temperature of the atmosphere. A calorie is just another unit of measurement with which to become familiar. The definition usually given is this: A calorie equals the amount of heat required to raise one pound of water to 4° Fahrenheit. One pound of water equals about one pint. Fats yield the largest amount of heat, therefore they are richest in calories. Carbohydrate foods yield the next largest amount of heat. Carbohydrates are composed of starches and sugars together with considerable cellulose or bulky fiber, in most instances, and, rightfully, form the major part of man's diet. The protein foods also yield some heat and energy, but unless taken in excess, protein foods, for the most part, are utilized for growth and repair of tissue. In fact, protein foods are too expensive to be used as fuel foods—expensive to the pocket book but, most important of all, expensive to the bodily mechanism, for, in excess, they throw so much extra work on the digestive organs, the kidneys, and the heart. All meats should be taken in much greater moderation than is commonly practised in the United States. Hard muscular work does not increase the requirement for protein, but a large amount of muscular work does make an insistent demand for more energy-producing food—more carbohydrate, starches, and sugar. Mental work makes no demand for extra protein or for extra energy-producing foods.

The human body, like other machines, not only requires

*Read before the Annual Conference of County and City Health Officers and the Public Health Nurses of Kentucky, May 15, 1920, Louisville, Ky.

fuel, but also water to keep it in running order. How far would a locomotive carry you without water in its boiler? The human machine requires water, not only to "make it go" like the steam engine, but also to assist in its actual growth and repair, for, unlike man-made machines, it is able to repair and renew its own parts. As 66⅔ per cent of the entire body is composed of water, large quantities of water must be taken in food and beverage in order to supply the constant bodily demand.

What Minerals Are Essential

Several mineral substances are essential for the growth and maintenance of the body. The three requiring our special attention are phosphorus, iron, and calcium. The necessary sulphur, potassium, chlorin, fluorin, magnesium, manganese, sodium, silicon, and iodin will usually be supplied if the requirements are met for phosphorus, iron and calcium. Phosphorus is as important to body growth and maintenance as protein. It is as widely distributed as protein, being found in every active cell of the body. Brain and nerve tissue, blood and lymph, are rich in their phosphorus content. With calcium, phosphorus helps to give rigidity to the bones. The foods from which this essential element is obtained are egg yolk, milk, vegetables, fruits, grains, and fish. Iron is also found in the structure of all the active cells of the body. Every little red blood corpuscle contains iron, that element essential for carrying the necessary oxygen to the body cells. Only a small total amount of iron is found in the body, almost no reserve being kept in supply except in very young babies. At birth babies bring with them a special supply to carry them over the first few months of adjustment to their new environment. Then, throughout later life the amount of iron excreted about equals the amount taken in. The important thing for us to remember is that each individual needs a constant supply; otherwise anemia is apt to result. Most of the leading authorities consider that the medicinal sources of iron are not so available to the human system as those compounded with our foodstuffs by nature. The iron found in the pharmacopeia is quite unlike that in our foodstuffs. Neither does beef juice longer hold its former high place of esteem in the treatment of anemia. The best, most available sources of iron supply are found in egg yolk, spinach, dandelion, celery, cabbage, string beans, carrots. Potatoes and other vegetables and fruits also contain available iron.

Calcium in combination with phosphorus makes the bones and teeth strong and firm. The ability of the blood to coagulate depends upon the amount of calcium salts it contains and the normal behavior of the muscles and nerves is controlled in large measure by the calcium content of the solution in which they are bathed. Calcium is constantly being metabolized. A measurable amount which is excreted daily must be replaced. If the replacement is not made, if sufficient calcium is not ingested to supply the demands of the body, the bones and teeth will be drawn upon to make up the depletion. This effect may be noticed more quickly in the growing child or animal or in the pregnant mother. The sources of supply of calcium are milk—the richest of all foods in this salt—the leafy vegetables, such as spinach and cabbage; also, cauliflower, celery, string beans, carrots, onions, potatoes, fruits, bread, and whole grains.

The Vitamine Requirement

The vitamines are food accessories essential for the growth and maintenance of the body about which little definite knowledge is as yet available, except that the diet is inadequate without them. Vitamine requirement is now a well established fact. Pending more complete and conclusive research by the British, French, and American experts now studying this vital problem, the part for us to play is to see to it that our families recognize the value and necessity of eating such foods as will supply these necessary substances for their bodily needs. Vitamines are found in milk, fresh fruit and vegetables, particularly in the leafy vegetables. Fresh meats contain small quantities of vitamine substances. Lemon juice is said to be particularly rich in them and freshly germinated beans, peas, and grains also. Perhaps we may learn to include in our diet several of the excellent Chinese dishes made with germinating grains or legumes as a basis. A well balanced ration, a mixed diet—especially recognizing the value of milk, fresh vegetables, and fruit—is the one best guide to the proper nourishment of the body.

Children are, of course, the paramount consideration in all our health work. They are just beginning life and it is our privilege, and duty as well, to so guide the selection of their food—the blocks with which is builded the body as a whole—so to guide the diet of the prenatal mother, the infant, the pre-school child, the school child—that when he attains adult life he will be the rich possessor of a sound body equipped with a sound mind.

Education and the Dietary

It is our duty to teach them to respect food. Under our guidance children should learn to use food to its best advantage for it is the source of their mental and physical force. During their early years they may learn that the satisfaction of the palate should not be the chief aim of life and that our foods nourish us whether we like them or not. Food that is distasteful—if retained—is as completely, though perhaps more slowly, digested as that which is enjoyed. Just let the food slip by the palate and old Mother Nature will do the rest. Oftentimes foods to which children show an aversion may be so disguised as to meet their approval; for instance, milk may be given as soup, cocoa, pudding, and frozen desserts. Cereals may be given in various forms of dessert, with cooked fruits, and as soups.

"With milk freely supplied and an average of one egg a day, there is no call for the introduction of meat into the diet until after a child is seven years old," according to Mary Swartz Rose. Children require protein food, but meat is not the source from which to supply this requirement, for in the intestines of the child of seven years and younger the putrefaction of meat takes place very rapidly. Adult dogs and cats will thrive on a meat diet on which puppies and kittens often develop convulsions. The same condition is true of children. The one best source of protein food for children is milk. Every child from one to fifteen years will be healthier, happier, hardier, and eventually a more effective adult if given at least one quart of milk each day. This may be taken as milk or cooked in the food in various ways.

The child of fifteen years should consume more food than an adult of the same size. He needs more food for his body is growing rapidly and his needs for the necessary material with which to build new tissues are great. Then, too, the youngsters of this age and younger are usually very active, and muscular activity calls for more energy producing food.

All foods that are good for childhood are also good for adult life. The converse is not true, however, for the stomach of a child should no more be called upon to digest the ordinary man's dinner than his muscles to lift

or carry the man's burden. With almost no exception, it will be found it is much harder to train the adults in the family, the father and mother, and particularly the grandfather and grandmother, in health habits than it is to train the child himself. But it can be done.

In infant welfare clinics our two professions are doing much to promote a universally sane practice in the feeding of babies. After they graduate from the baby clinics, though, there is still great need for careful scientific consideration of the diet. When a calf is weaned, the most successful farmer does not give the young thing the same diet as its mother. He realizes that the digestive apparatus of that calf is not equal to the task of digesting the same food as its mother. Why, then, expect a baby to thrive on nibbles from the plate of Daddy, Grandmother, and the grown-up children?

To correct many of the mistakes made in the diet of children of school age, nutritional clinics have been established in many cities with astonishingly happy results. Usually, the children found to be 10 per cent underweight are the ones privileged to enter these nutrition clinics; 7 per cent underweight has more recently been found the safer condition for entrance.

Nutrition Clinic an Aid

In order to establish a successful nutrition clinic, the nurse finds the first requisite is a doctor interested in keeping children well and full of "pep," a doctor interested not only in children but also in preventive medicine. The next requisite is a set of scales and a measuring tape or rule firmly fixed in a permanent place and easily accessible. Then come weight charts to be hung on the wall, booklet records for the children to keep themselves, colored stars, and a few other accessories; also, provision for the mid-morning and mid-afternoon lunch; blankets with cots or mattresses for the mid-morning and mid-afternoon nap or rest period are necessary in an all day school.

Parents soon become interested and will often ask numerous questions after the class is over. "Why should she and her Johnny always have to sit at the foot of the class?" is often the inquiry of the fond, yet unwise, mother. When told that if Johnny would stop drinking coffee and take his afternoon nap regularly he might gain the necessary weight to bring them both up to the head of the class, Johnny usually does stop drinking coffee and does take his afternoon nap.

The competition for gaining weight is always a great help in these classes and a very happy help as a rule. The Child Health Organization, 156 Fifth Avenue, New York City, has some valuable literature on this subject and will glady advise with any of you in organizing and suggesting these classes. A ready, easily understood, comprehensive guide on the subject of nutrition, for daily use, may be found in Rose's "Feeding the Family." I earnestly urge that every nurse make careful inquiry into the diet of all of her families, then consult carefully her references on the subject, seeking some means through the bodily intake of foods of helping to prevent much unnecessary suffering. Every worker who is not a physician should always consult the chief in cases of illness.

The successful Public Health Nurse is the counselor in health of every family in her district. Her aim in life is to cooperate with her chief, the Health Officer, or the doctors with whom she serves in reducing the prevalence and amount of illness and in decreasing the death rate. A knowledge of nutrition will materially aid her as well as the doctor in this laudable undertaking.

THE CHILD WHO DWELLS AT THE HEAD OF THE HOLLOW

By JOHN F SMITH, Professor of Social Science, Berea College Academy, Berea, Ky.

THIS is written as a plea for more adequate medical care for the unreached people of the Southland. By the "unreached" I mean those who live in remote corners, at the back of old fields, far down in the swamps, high up on hillsides, at other secluded spots which the busy workaday world is inclined to pass by. These are the people, both white and colored, who do not have a sufficient amount of nourishing food, do not possess comfortable houses; they have few of the necessities and fewer of the amenities of life. They are not touched in a very helpful way by our public schools, are rather generally passed by by our colleges and universities for they are too poor to pay the price. They must be content, or at least half-content, with a system of very dogmatic religion. They are not trained in any effective manner to do their share of the world's work with credit to themselves and their country. They dwell for the most part in houses poorly fitted for human habitation. These houses are not all far away. Many are located on the margins of prosperous neighborhoods, and most of them are close enough to some prosperous neighborhood to be seen on any clear day from lofty hilltops.

A very large number,—and those I am most interested in—dwell in remote regions of the open country far up in lonesome valleys or back in the deep forests of the lowlands where the smell of growing things is ever fresh and where the dew lingers long on leaf, the grassblade, and the petals of wild flowers. They dwell where the groundhog whistles to his mate by day, basks leisurely in the sunshine, and scuttles into his hole at the approach of the traveler. Near their homes the gray and the red squirrels chase one another among the tree tops, cut the wild nuts, and destroy the nests of songbirds. Great hawks circle over the forests and scream by day, and the hoot owl and the barn owl mingle their loud screams at night time. It is away out and up across field and pasture and timber lands where boulevards dwindle down to squirrel trails and fade away at the roots of giant trees.

Out in these lonesome places they get sick, suffer, and often die. They have not had opportunity to learn the laws of health. No one has ever been there to teach them. Those who have gone among them have usually gone as missionaries with little knowledge of their real needs and their traditions. A Bible and a song book have usually been taken—excellent things in themselves—but these have not cured pellagra, have not prevented babies from having enteritis, whooping cough, measles, diphtheria, worms; nor have they taught people how to avoid typhoid and tuberculosis, dysentery and pneumonia. Some progress has been made towards preparing them for

An ancient church in which is still preached sermons on "total depravity," but thinks recreation ungodly.

Is it to be wondered at that boys quit school at the fifth grade when even the new schoolhouses lack shade and a place to play?

the Kingdom of Heaven but little has been made towards preparing them to become healthy mothers and fathers, to take proper care of their babies, to grow into their full stature, and to do their share of work here in this Kingdom of the World.

There are more of these unreached people than our learned educators and other conventionally minded people are willing to admit. They may be numbered not only by hundreds and thousands but by millions, actual millions of men, women, and children from whom the ministering hand has been too long withheld. If anyone doubts that the unreached exist in so large numbers let him but "go forth under the open sky" and look about him with sympathethic interest and penetrating eye. He will doubtless make some surprising discoveries.

I am deeply interested in these folk of the open fields for two particular reasons: First, they are my people, and I want to see the same medical care, the same opportunities for practical education, for an effective, soul-inspiring religion, and the same chance for full development brought to them as are brought to the most favored in the land, and, second, because the blood and will and fiber that have made more than half of our successful leaders in education, religion, and business are to be found in great abundance among these undeveloped sons and daughters of our rural families. When we examine a list of our leaders in thought and progress we discover early that a very large percentage were born and grew up in fields and pasture lands where wild flowers bloom and sharp eyes peer from treetops and fish-folks play in the streams. Here are a few of our leaders who were born far enough away from the smoke of cities to see the sun rise every morning in a clear sky: Elbert H. Gary, John D. Archbold, Frank Vanderlip, William Dean Howells, Champ Clark, Thomas A. Edison, George M. Reynolds, David Lloyd George, John J. Pershing, Jane Addams, Maud Ballington Booth, Russell Conwell Ben B. Lindsey, John Mitchell, Robert E. Peary, Henry Ford, James B. Duke, John H. Patterson, Joel Chandler Harris, Frank Woolworth, John N. Willys, Edward C. Simmons, John G. Shedd, Darwin P. Kingsley, Percy H. Johnson, Thomas Nelson Page, Dan Willard, and a host of others. And there are scores and hundreds of lads born out among ferns and dogwood blossoms close to the haunts of the wood thrush and the oven bird who under favorable circumstances would grow as strong and great as most of the men whose names are mentioned. They are born amid all the advantages and joys of the open country side and inherit all the disadvantages and depressing hardships that isolation frequently brings.

It must be borne in mind that not all the children born in remote regions belong to the unreached class. The country has its wealthy people as well as the city, and also its slums. Many of the dwellers in the open country have the means to bring the best of everything to their doors, but others, whose number is millions, do not have such means. The first group can purchase the benefits of the best medical skill and hospital service, the latter cannot. It is the latter class from whom I plead.

The "old oaken bucket" shown is a sorghum pail, and the sentiment attached to the picturesque does not keep the well from being filled with "bess bugs" and typhoid germs. What of the people whose sole water supply is a well like this?

Are these unreached people in need of better medical attention?

For a whole life time I have seen children born in remote places grow and suffer and develop into mere fractions of men and women because a ministering hand was not held out to them in hours of need. The hand was not present and the means were not within reach to bring it near. I have seen little ones of promise overtaken by physical ailments that cut short their lives and left only scars and memories in the hearts of their parents. These ailments could have been prevented had the skill and the knowledge been near to minister to the little sufferers. The game of life and death was played in the absence of a trained hand, and death won in the lottery. Often have I seen a white casket, or a homemade coffin, a procession of farm wagons, and heard low

sobs of inexpressible grief when the life light of a wee one had been snuffed out because the forces were not at hand to protect the little one from the relentless foes of childhood. For generations such things have been going on in the open country of the Southland, and they will continue until a public conscience is awakened in every neighborhood that will demand a skilled medical officer and a highly trained public health nurse within reach of every home. And this matter of saving child life must be taken upon a sound business basis. Church boards and missionary societies have long looked upon the unreached poor as objects of missionary effort and charity. A few unskilled people have been "sent" out with some enthusiasm, but often with little common sense, who have pottered around in remote corners, talking religion here, holding prayer-meetings there, preaching a creed at other places, doing the only thing they know how to do to help the people, and doing it all for charity's sake and from the missionary standpoint. The majority of these "workers' have done nothing to teach mothers how to care for babies, or to instruct fathers how to provide suitable recreation for their sons, or to offer wholesome, funmaking entertainment to young men and women, or to convince people that typhoid and tuberculosis can be prevented. They may have saved some souls, but certainly they have saved very few lives. They probably did the best they could, certainly all they knew how to do. But the very things that the unreached people need most cannot be learned in a theological school or a missionary training school of the average sort. The only place to learn this first aid for first service is in a hospital or a medical training school. Sunday schools don't bring much relief to children who are underfed and infected with hookworm and other diseases. When Jesus found a sick man He first healed him and then taught him a great lesson of love and life. He did not visit with him and commiserate wtih him in his suffering; He made him well so his mind could be a suitable receptacle for a great idea.

The Pious Attitude Toward Death

One of the first things which the unreached people need is a changed point of view regarding the cause of death. Too long has the responsibility for the deaths of children been laid by tens of thousands of pious country folk at the feet of Providence. In their helplessness the very poor have sought a cause for all their woes, and they have learned to think—have often been taught to think—that the Lord goes about over the earth picking out choice human flowers whom he takes away to add beauty and sweetness to the halls of paradise. I do not doubt that these departed child spirits do add grace and exquisiteness to the bowers of bliss, but it would be far more practicable and infinitely more humane and Christlike for every neighborhood in the land to take the necessary steps to have these child spirits remain here on earth for a few scores of years to add grace, beauty, and economic values to our fields and hearthstones. Our schools, churches, political institutions, and homes need their strength, presence, and wisdom much more than paradise needs their spirits. And it is not too cruel to say, for someone must say it, and say it till it arouses ire and opens pocketbooks, that one of the chief reasons why so many choice spirits go to dwell in paradise rather than on earth in the homes of men is the fact that tens of thousands of substantial farmer folk have not yet reached a point where they consider it a religious duty to open up their purses to pay the salaries of the nurses and public health officers who could save their children. It is a poor kind of religion that shoulders upon Providence a responsibility that rightly belongs to human beings; and it is a poorer kind of service that sends people out to minister to the unreached poor as an act of charity rather than on a sound business basis. The old way may save the lives of the missionary societies but it certainly does not save the lives of the people.

But there are hundreds of thousands who are too poor to pay. These must be reached at public expense, both for their own sakes and for the sake of the state that claims them. The state is certainly under as much obligation to take care of the bodies of the living poor as it is to bury their bodies when they die. It would be a crime against decency and civilization to allow the bodies of the dead poor to lie and decay in the sight of the living; is it not also a crime to allow the bodies of the living to walk about among the strong and healthy maimed, diseased, neglected, infecting the well with diseases that will also carry them away?

The Unreached Among the Prosperous

What evidence do we have that there are unreached children even in prosperous neighborhoods?

In Virginia where the health forces are among the most efficient in the Southland, recent examinations were made of school children in a number of counties and the following figures were made public:

In one county 3,489 children were examined, 20.9 per cent had defective eyesight, and 29.8 per cent had defective teeth. Teachers in another county examined 502 children, finding defective eyes in 29 per cent, and defective teeth in 61 per cent. Altogether 22,418 children were examined, 22.3 per cent of whom had defective vision, and 46 per cent had defective teeth. Virginia children have eyes and teeth that are no better and no worse than those of other southern states. We do not know what defects do exist among the country children; only a few of us have ever taken the trouble to look into the matter, and none of us has made very thorough investigations.

But defects enough exist. I have seen children in the homes of the poor with teeth rotting out, with eyes grown raw with trachoma, with feet and legs covered with "toe itch" and "dew poison." I have seen others with eyes threatened with poison ivy, some with great gashes in their feet bandaged with very dirty rags, many seriously afflicted, and only the most primitive kinds of treatment employed. In tens of thousands of poor homes it is not customary to consult a dentist until teeth are too far gone to be saved. In these same homes an oculist is never consulted. "Specs" are sometimes bought by the old folks, but are looked upon as a sort of disgrace for the young. These "specs" are usually purchased from itinerant eye doctors, who are usually about as well informed on eye troubles as an infant is on the nebular hypothesis. Salves and eye-washes are employed to "cure" trachoma; bitters are taken for colds, back-aches, and countless other troubles; kerosene is given for the croup; hot onion poultices are applied to the soles of feet to draw out the fever; linn ooze and sweet milk are applied for a "hurtin' in the eye," and numerous other remedies are resorted to by those who were brought up under the care of ancient grannies and their more ancient medical science. In thousands of homes flies are allowed to swarm by day and by night, and, when a child becomes sick of enteritis, catnip tea and turpentine are given to cure it. In other thousands of homes a throat trouble in a child causes little concern, and a doctor is often called just in time to see a baby die of diphtheria. There are many mothers yet living who take their babies to a neighbor's house where children have whooping cough to "let um ketch it

an' git over it while they are still little," not dreaming that whooping cough is just about as fatal these days as diphtheria. In these same homes almost no time is devoted to prenatal care of mothers. The result is that mortality among mothers at childbirth remains almost the same as it was a quarter of a century ago. If anyone is inclined to doubt that such medieval remedies are still resorted to, and many others much more hopelessly bizarre that might be mentioned, he has only to "go forth under the open sky" and list to ancient grannies and their teaching.

Why Is an Unreached Family?

Why do these unreached families exist?

In our land of wealth and democratic institutions it is clear that such things should not be; but they are, and they exist for several reasons, some of which follow:

In most rural neighborhoods there are no hospitals. We have not yet reached the stage in our civilization where we will provide adequate hospital service for all our poor at public expense. Virginia has three public hospitals for tuberculous patients; West Virginia has four; North Carolina, three; South Carolina, four; Alabama, two; Tennessee, three; Kentucky, three. Each one of these states will some day have a free public hospital in every county, but that day is a long way off.

Where hospitals do exist, many people are afraid of them. They fear to go there because, according to their own testimony, something may be done to them "that may hurt." Their fathers and friends have always died fairly well without a hospital, so some of them prefer to die at home rather than take chances on getting well at a hospital. One of the problems of our health departments is to convince the poor and timid that hospitals are institutions of service rather than of torture.

Another great barrier is the hospital fee. Many a person dies at home because hospital fees are prohibitive to the very poor. Men of wealth can render no greater service to humanity than by constructing hospitals at strategic places in the remote open country and endowing them for the use of the poor who must die without such service unless men of wealth—or the state—take this all important step.

As has been said, thousands of the unreached poor dwell far away from the county seats, where live the majority of doctors and nurses. To reach them, the

A home at the head of the hollow. Homes like this shelter thousands of hopeful, honest folk, far removed from the trained service of a nurse or doctor. Home remedies are employed and desperate chances taken with illness.

Wreckage of a primitive corn mill. Note the home-made turbine of poplar, the sluice, and the stack tower that supports the sluice. No trained physician is within twenty-five miles of this spot, and no nurse ever visited the neighborhood.

In remote places like this the only highway is a trail. Here the roar of the rushing stream, the scream of the hawk by day and the owl by night mingle with the moans of the suffering child.

A main road between the railroad and twenty thousand people. Given a very dark night, a desperately sick child twenty miles away, a midnight call for a doctor, what would be the result? The mule in this picture has fallen from exhaustion, and the farmer still has twenty miles between him and the market.

doctor or the nurse must in most instances travel over roads that are poor at their best and almost impossible at their worst. Not all distress calls are answered. Doctors and nurses are but human and became exhausted with constant service. The majority go when a call comes, whether the distance be great or small; but distance and bad roads militate against the sufferer and turn the tables in favor of death.

In homes like this the neediest often dwell. Cleanliness is next to impossible in such houses, and a child from such a home is often a source of danger to other children about it.

In most isolated neighborhoods there is no nurse at the disposal of the people. The number of country nurses is increasing, but tens of thousands of people suffer and died before the ministering hand of a nurse can reach them. A few weeks ago Virginia reported 143 public health nurses, West Virginia 70, North Carolina 15, South Carolina 75, Alabama 60, and Kentucky 80. These same states claimed that a total of about one thousand three hundred nurses are needed at once. This claim is modest enough. If this number were multiplied by ten it would more nearly represent the number needed to care for all the sick and the well in the outlying districts.

In numerous counties the public health forces under present conditions are hopelessly inefficient. However sincere and capable the members of county boards may be, they can never render the maximum service until a highly trained public health officer whose salary does not depend on fees is placed in every county, and nurses enough are put under his direction to reach every home in his territory.

Much suffering may be traced to the untrained midwife, who is the sole arbiter between life and death at the birth of children in thousands of poor homes. Trained medical attendants are not always inclined to give full credit to the midwife for the good she does. I have often heard her work spoken of lightly but have rarely heard it praised. It must be remembered that she renders an invaluable service to mothers who are too poor to afford the services of a trained physician or a nurse, but it must also be remembered that she is often responsible for serious tragedies in both mother and child. It may be safely said that she always does the best she knows,—and she often knows more than she gets credit for,—but in emergency cases she is helpless. In such cases only the skilled hand can prevent disaster.

Isolation is partly responsible for the unreached family. The great currents of progressive thought that influence the masses to move forward dwindle down into feeble mental rills before the marginal people are reached. So are the country schools. These are often taught by poorly trained teachers,—young women mostly who have a smattering of a few subjects but who, at least in some states, are rarely trained to do the most important thing first. Impoverished religious services contribute a large share to the untoward conditions. The ministers are generally untrained, the singing is prone to magnify the sadness of death and the imaginary glories of heaven; the sermons are usually depressing and burdened with dogmatic creeds rather than with measures for relieving and preventing physical suffering.

Still another cause lies in the fact that thousands of the poor folk are born with defective physical and spiritual foundations to build on. Malnutrition, improper care during infancy, nicotine poison, morbid thoughts, and other blighting agencies have done their deadly work for generations, leaving only fractions of men and women to pass on their weaknesses to other human fractions in the future.

The Menace of the Unreached Family

Without intending it at all the unreached family constitutes a menace to the health, morals and progress of the neighborhood. And the danger goes beyond the bounds of the neighborhood where the family dwells. When people have little knowledge of the common things of life, the great principles of Americanism mean little to them; when they are poor, they add to the poverty of the Nation; when they have only an antiquated form of religious

On this road, the main outlet for two entire counties for a century, a four-mule team is necessary to pull the mail wagon. No doctor or nurse could make time over this highway during the winter months.

One may readily understand why the principle of sanitation and health are not taught to the isolated poor when a schoolhouse like this is the only kind available.

service, they are liable to develop into fanatics, or they will become so austere in character that they repel all young folk from the church. When women or men are unlettered, they become a potential factor for danger at the polls; when one woman in a remote neighborhood is immoral, she will contaminate many homes; when one child becomes ill with a contagious disease, every child about it is in danger.

I have recently made some studies of delinquency among people in remote neighborhoods and have found rather discouraging things. In one neighborhood more than thirty women and girls were known to be immoral, and more than a dozen young girls gave birth to illegitimate children in a few years—a condition that may be traced not so much to depravity as to a lack of proper opportunities for wholesome recreation. Almost similar conditions were found in other neighborhoods. This, however, is not to be taken as an index to the moral status of all remote neighborhoods.

The menace of the unreached family in its many forms is perennial. Nobody's child can be entirely safe until everybody's child is adequately cared for.

A Reconstruction Program

In removing the danger that exists in the home of the unreached family certain steps seem advisable.

(1) Demonstration in care of children and mothers and in means of preventing diseases must be held in the remote neighborhoods. Talk doesn't get the people very far. Things must be done that will be remembered and talked about when little groups get together. The work of the Rockefeller Sanitary Commission during its campaign against hookworm in the Southland was the best practical demonstration we have ever had on a large scale

(2) The whole truth must be told at conferences. There is often a tendency to report great progress and leave unsaid the things concerning the imperfections of health programs. Nobody is reaching everybody. No program is likely to function in the fullest sense. We must recognize that there are unreached people, and that it is our responsibility to take care of them, and we must acknowledge that they are found in our own neighborhood.

(3) Some wise person who knows the difference between condensed milk and "shawnee" must invent a menu for country children made up of the things the poorest mother can obtain. She has only certain things at hand to eat and to feed to her children. She has fat salt pork, beans in season, wild "sallet," dry peas, coffee, sorghum, fruit, garden vegetables in summer, corn bread, and, usually, milk. Out of what she has someone must work out a menu that will be good for the growing child. There is no need of talking to her about animo-acids, anti-scorbutic vitamines, fat-soluble A and water-soluble B. It must be in terms of beans, gravy, milk, bread, wild "sallet," peas, etc. What she has is about all she can get,—and it will be a wise nurse who discovers the combination that will satisfy the mother and the stomach and muscles of the growing child.

(4) It will be necessary for courses in health and sanitation to be required of all students in all our educational institutions,—especially in all public and normal schools. Any normal school that does not offer suitable courses in health work and in the prevention of common diseases deserves to be ostracized by the public. Any head of any normal school who does not put the major emphasis on child welfare rather than on theoretical pedagogy deserves reconstructing, to say the least.

(5) Health institutes must be held for health workers and for the public. On Chautauqua platforms speakers are inclined to talk about everything else except enteritis, pellagra, hookworm, and pasteurizing milk. The public ought to have more lectures on the prevention of diseases. And these institutes must be carried into remote neighborhoods where the greater need lies.

Lecturers trained especially for country service ought to be available. Those who succeed best with the unreached poor in the open country must know the difference between a barn owl and a whippoorwill. And no mistake will be made if those who can see from the level of the cabin door be brought before our training schools for nurses in the cities, that the call of the open country may be duly presented by those who know from experience rather than through hurriedly made surveys.

(6) Programs made especially for the people of the open country must be employed. If a program succeeds in the city there is no conclusive evidence that it will succeed in the sparsely settled country at the head of the creek. Human nature is very much the same everywhere, but the line of approach must differ in different places. One of the things that will for a time militate against the success of the ultra-rural program is the fact that most of the workers who have gone into the remote neighborhoods have gone on the missionary basis. People must be convinced that health workers do not come to preach conventional sermons and hand out second-hand clothes. "It must be a fifty-fifty proposition," said a nurse to me recently. Country people have as much to give as they have to learn,—and all who work in rural neighborhoods should recognize this fact.

(7) All nurses and health officials who plan to go into the outlying fields should have their attention called to the larger spiritual aspects of the work they are to do. It is not a mere matter of applying bandages, using antiseptic washes, bathing babies, pasteurizing milk; it is ministering to people in a way that will enable them to have life and have it more abundantly. The worker in the head of the long, lonesome valley must be much more resourceful than the worker in the city. Human souls often need healing as well as human bodies. The larger things in the spiritual life need emphasis quite as much as the simple things connected with sleep, food, and personal cleanliness.

"He gives nothing but worthless gold
Who gives from a sense of duty;
But he who gives but a slender mite,
And gives to that which is out of sight,
That thread of the all-sustaining beauty
Which runs through all and doth all unite,—
The hand cannot clasp the whole of his alms,
The heart outstretches its eager palms,
For a god goes with it and makes it store
To the soul that was starving in darkness before."

THE AMERICAN JOURNAL OF NURSING

The July issue of the *American Journal of Nursing* presents the proceedings of the twenty-second convention of the American Nurses' Association, held at Atlanta, Ga., April 12-17, 1920. Several papers printed in this issue give in detail several important phases of the work of the Association, among which are:

"United States Public Health Nursing Service," by Lucy Minnegerode; "Aspects of Private Duty Nursing in the South," by Frances J. Patton; "The Future Outlook of the Private Duty Nurse," by Winifred Boston; "Peace Time Program for Mental Hygiene," by William Barclay Terhune; and "Accredited Schools of Nursing," by Elizabeth C. Burgess.

MICHIGAN TRAINING SCHOOLS FOR NURSES SECURE RECRUITS

By MISS MAUD McCLASKIE, Instructor of Nurses, Farrand Training School for Nurses, Harper Hospital, Detroit, Mich.

THERE are actively engaged in the pursuit of the nursing profession 1,731 graduate nurses in the state of Michigan. Of these, 1,351 are Red Cross nurses, 40 are full time Red Cross county nurses, and 30 are Red Cross instructors. The total enrollment of student nurses in accredited training schools is 1,710. This makes a total of 3,400 nurses to furnish service for a population of more than three million people. In addition to this, conditions are modified by the consideration that nursing service is largely concentrated in and about institutions, and largely in cities. The Michigan Hospital Association early last March recognized the necessity for recruiting one thousand student nurses for Michigan training schools. This was undertaken, not alone because of the necessity of caring for patients in hospitals, but because the broadening of nursing activities, as shown by the preceding figures, called for ever increasing numbers of trained workers. It is apparent not only that more nurses are needed, but that it is necessary that these new nursing recruits shall be drawn from classes where good home training and educational qualifications constitute a part of their preliminary equipment upon which a nurse's training will be superimposed. Then the performance of exacting and highly specialized duties will be committed to the public service after their graduation from hospitals.

Organizes for Action

The campaign for the one thousand recruits, conceded necessary at the present time in Michigan, found its impetus in the demonstrated needs. The work was initiated by the Michigan Hospital Association and was financed by them but its immediate direction and execution was placed in the hands of a Central Committee composed of superintendents of training schools for nurses, hospital superintendents, and the secretary of the State Board of Nurse Examiners, so that coordination and proper subservience to the larger aspects of the situation were not lost sight of at any time. This Central Committee in turn appointed local chairmen to correspond to the Congressional Districts of the state. The Central Committee furnished the local chairmen with literature for the instruction of speakers and with special literature for distribution in all of the high schools. Too great divergence of method and appeal was guarded against by the employment of a field secretary of skill and experience in organization. This secretary was not a trained nurse, but she understood the educational aspect of the campaign, was interested in it from the viewpoint of a humanitarian movement, and, being a trained organizer, was gifted in selecting and securing the services of people who were representative in the community and combined influence and interest and experience as a contribution to the campaign.

The organization of the local campaign in Detroit was typical and has been outstanding from the standpoint of its intensity, the marvelous response accorded to its local committee, and the attitude of the public to its every effort. The chairman of the local committee in Detroit was Miss Maud McClaskie, instructor of nurses, Harper Hospital. Other members of the committee included Mrs. Henry B. Joy, representing Grace Hospital; Mrs. Joseph B. Schlotman, representing Harper Hospital; Mrs. W. H. Burtenshaw, Woman's Hospital; Miss Ellen Cowgill, in charge of the Young Woman's Christian Association; Miss Grace Ross, head of the Nursing Department of the State Board of Health; Miss Theresa B. Haley, representing the League of Catholic Women; Miss Lena Lake Forest, who is chairman of the nursing activities of the local Red Cross Chapter as well as the president of the state Business Women's Association; Mrs. Wilfred C. Owen, secretary of the Industrial Women's Service Center; Miss Ira M. Gaily, Samaritan Hospital; Miss Mabel A. Thompson, assistant director of the Industrial Women's Service Center; Miss Lulu B. Durkee, assistant principal Harper Hospital Training School; Miss Theresa Martin, St. Mary's Hospital; Miss Elizabeth Cleveland, in charge of the Vocational Guidance Department of the Detroit Public Schools; and Miss Helen Livingston of the Cass Technical High School.

It will thus be seen that vital centers of public welfare as well as the interest of the entire nursing and hospital field were at once secured. It then became necessary to enlist the aid of the moving picture houses of the city and it is interesting to note that their response was immediate and they considered their services given to an educational interest and a public good. Forty-nine theaters carried a small advertisement on the screen daily at all performances for one week. The Committee, a highly representative group, were photographed by a motion picture house and their pictures displayed on the screen in every motion picture house in the city for one week at a time. Publicity appeared in successive and graduated announcements in the daily press and it was centralized because the community union, representing ninety charity organizations, gave the Recruiting Committee their publicity service. So well did they carry the tone of the campaign, and so generous were the newspapers as to space and interest in the project that a wonderful interest was soon manifested by all groups of people in the city and at once the Committee were solicited for campaign articles for such periodicals as the *Business and Professional Woman's Magazine*, the *Detroit Club Woman*, the *Wayne County Medical Bulletin*, and the *First District Bulletin* of the Michigan State Nurses *Club Woman*, the *Wayne County Medical Bulletin*, the Association, and the *Y. W. C. A. Triangle*. In planning the campaign the student nurses's body, representative of the various hospitals, were added to speak to the high school students of the city, appearing in uniform. The Vocational Guidance Department of the city schools met the Committee with a wonderful response and five thousand pupil nurses, including public and parochial schools, were spoken to; literature was distributed to the students and one in every ten placed with the speaker a request for further information on nursing. Stereotyped appeal for public commiseration for suffering humanity gave way to a rational consideration of all the elements that enter into the situation. Facts a plenty were placed in array to demonstrate the need for

nurses for both the present and the future health of the community. The relationship of the nurses to the economic interests of the community, the security of the future generation, as related to their health and their happiness were pointed out. In effect, the scientific and educational situation of the relationship of the nurses to the community was revealed. Constructive health activities, free, though unrelated to charity, but definitely bound up with the responsibility of the community to its children, and the immediate functioning of a world free from the impediments of ill health, were made clear by arguments in some cases, but generally by word pictures.

Depart from Emotional Appeal

The departure from the emotional appeal had its bearing on nursing as a profession and, so interpreted, nursing becomes a profession, not a job; the people were made to see that the recruits must have preliminary preparation and personal qualities as well as proper professional education to make them able to function in these relationships to the public.

The shortage of nurses following the law of supply and demand has served to increase the fees for nursing services and has helped to place emphasis upon nursing as a career. Thus nursing is not urged upon the young women of today entirely as a personal duty to the uncared for, but as a field offering an opportunity for remarkable personal service and unlimited possibility for self-realization and self-expression, as well as a career which furnishes a reasonable standard of good living. It is pointed out as being interesting and being filled with a progressive social outlook. It is placed on an educational basis and constitutes what will assume an educational relationship to our universities and colleges. Culture in its last analysis is an interest in, and a sympathetic understanding of human relationships. Reciprocal influence with mutual teaching is the general law of education, and these constitute the ideal of objective of health service. The past history of nursing does not even hint of its possibilities in the way of new departures.

AMERICAN DIETETIC ASSOCIATION MEETING

The annual meeting of the American Dietetic Association will be held in New York City October 25-27, with headquarters at the Hotel McAlpin. The program includes subjects of interest to the dietitian in public health service, to the hospital dietitian, and the hotel dietitian; in fact, the discussions are of value to all who are in any wise concerned with either scientific or practical phases of food service. The program follows:

MONDAY, OCTOBER 25

Morning Session

Meeting of the Executive Committee.

Afternoon Session

Section on Administrative Work: Miss Mabel C. Little, hospital dietitian, Norwalk, O., chairman.
General Subject: To What Extent Can Mechanical Equipment Replace Employees in Institutional Work?
The College Dormitory.
By Mrs. Elizabeth Grider, Cornell University.
The College Dining Room.
By Miss Cora Colburn, University of Chicago.
General Discussion of Equipment: Menu Making; Its Economic Aspect.
The Dormitory.
By Miss Elsie Leonard, University of Wisconsin.
The Hospital.
By Miss Marguerite Deaver, Mt. Sinai Hospital, Cleveland.
The Cafeteria.
By Miss Emma Baker, Whittier Hall, Teachers College;
By Miss Smith, War Risk Bureau Cafeteria, Washington, D. C.
Economical Buying for the Institution.

Evening Session

Address of Welcome.
By the president, Miss Lulu Graves, Cornell University.
Address.
By Dr. Alonzo E. Taylor, University of Pennsylvania.

TUESDAY, OCTOBER 26

Morning Session

Marketing.
By Miss Susannah Usher, Boston.
Application of Business Principles to the Organization of Institutions.
Training for Administrative Positions in Cafeterias.
By Mr. Roland White, the Colonnade Company, Cleveland, Ohio.

Afternoon Session

Section on Social Service: Miss Blanche M. Joseph, field dietitian, Emanuel Mandle Dispensary, Chicago, chairman.
The Supervising Dietitian in State Institutions.
By Miss Theresa A. Clough, Springfield, Ill.
Social Service in Dietetics.
By Miss Fairfax T. Proudfoot, University of Tennessee.

Evening Session

Diet and Dentition.
By Dr. W. J. Gies, College of Physicians and Surgeons, Columbia University.
The Dietitian in Public Health Work.
By Dr. E. A. Peterson, director of Department of Health Service, American Red Cross, Washington, D. C.
Diet and the War.
By Mrs. Mary de Garmo Bryan.

WEDNESDAY, OCTOBER 27

Morning Session

Address: Dr. Katherine Bement Davis, general secretary, Bureau of Social Hygiene, New York.
Address: Miss Emma Gunther, Teachers College.
Research in Dietetics.
By Miss Hilds Croll, Women's Medical College, Philadelphia.

Afternoon Session

Section on Teaching: Miss Katherine Fisher, Teachers College, chairman.
Dietetics for Nurses.
By Miss Lenna F. Cooper, Battle Creek Sanitarium.
Methods of Teaching Dietetics to Nurses.
By Miss Marion Paterson, Swedish Hospital, Minneapolis.
Review of Literature on Dietetics.
By Dr. Ruth Wheeler, Goucher College, Baltimore.

Evening Session

Address: Miss Sarah Louise Arnold, dean of Simmons College, Boston.
Some Dietetic Problems of Infancy and Childhood.
By Dr. Roger Dennett, assistant professor in the diseases of children, Post Graduate Hospital, New York.

THURSDAY, OCTOBER 28

Morning Session

(At Teachers College)

Economic Aspects of Buying Meats.
By Mr. John H. Kelley, buyer, Arthur Dorr Markets, Boston.

RESULTS FROM INTEREST IN HEALTH MATTERS

The *Statistical Bulletin* for May, issued by the Metropolitan Life Insurance Company attributes the record-breaking low mortality rate for last year in the United States to the war educational propaganada which instructed the public in hygienic matters, improved dietary standards, and centered attention upon the working conditions of wage earners.

If such concentration of effort has brought about these marked results, it may be generally accepted that a large proportion of the disease existing in America is preventable, says the *Red Cross Bulletin*, and far greater results are to be hoped for as time demonstrates the value of the health safeguards that are now being placed about children.

RUSSIA COMBATS HUNGER AND DISEASE

That 50 per cent of the people of Soviet Russia are hungry, though everybody is getting a certain allowance of food, is the declaration of Benjamin Turner, member of the British labor delegation to Russia. "The physical and material condition of the country is so bad they do not attempt to hide it. They have had a tremendous battle with disease. There have been one million cases of typhus, and scores of thousands of malaria and smallpox cases," states Mr. Turner.

The tragedy of all great cities is the tragedy of the child-life of the slums.—Robert W. Mackenna in "The Adventure of Life."

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

RACE STOCK AND MORTALITY

THAT racial differences might account for variations in mortality rates in given communities has been the general belief. The peculiar susceptibility of the Irish and comparative immunity of the Jew to pulmonary tuberculosis have long been recognized, and similar variations have been noted among certain races for other diseases.

The findings in the recent studies by Dublin and Baker[1] on the mortality of race stocks in Pennsylvania confirm those of Dublin's earlier study[2] of mortality of race stocks in New York, and reveal much interesting and enlightening data on the effect of immigration of European race stock on the demography of the United States; also on the question whether residence in this country has had any effect on the mortality of these race stocks since their arrival.

The native born of native parentage shows a mortality lower than that of the native born of foreign or mixed parentage, and lower than the rate for the foreign born. The foreign born, and the native born of foreign or mixed parentage, agree much more closely with each other than with the native stock. The death rates for the British, Germans, and Irish are greatly in excess of the rates for native born, but the rates for Austro-Hungarians, Russians, and Italians are more favorable. The higher rates among the first group mentioned explain the apparent exception at ages twenty-five to forty-four years, at which period the foreign born have a great advantage over the native born of foreign or mixed parentage. It will be recalled that immigration of the first group reached its highest point in 1850 to 1870. about thirty to forty years previous to that of the latter group, so that the deaths among native born of foreign or mixed parentage between the ages of twenty-five to forty-four were mainly of British, German, and Irish descent. These rates were higher than the rates for foreign born of ages twenty-five to forty-four, who were mainly Austro-Hungarians, Russians, and Italians.

Noticeable differences are evident when the mortality of race stocks in this country are compared with the rates in their own country. The death rate in 1911 per 1,000 males in England and Wales was 6.4 as against 8.4 and 8.7 for British born males living in Pennsylvania and New York respectively. The death rate for males in Germany was 6.4 per thousand in 1908-1913, as against 9.0 and 10.0 for Germans in Pennsylvania and New York. Italians in Pennsylvania and New York show little difference in their death rates from those prevailing in their home country. The Irish have lower rates at home. On the whole the rates are higher in Austria and Hungary than among their emigrants living in this country.

The extent of violence, excluding suicide, as a cause of death among Austro-Hungarians, Russians, Italians and other foreign born, is very great, and is undoubtedly the result of the perilous and unskilled occupations in which these immigrants engage. It is the most important cause of death among Austro-Hungarians and Italians, and the rates from this cause are several times higher than among the natives.

The Irish suffer extraordinarily from tuberculosis, though the Italian, Russian and Austro-Hungarians have low rates. Practically every foreign group shows higher cancer rates than do the native born. The Irish present the highest rates from organic diseases of the heart, pneumonia, and Bright's disease. The position of the Italians relative to cancer, organic heart diseases and Bright's disease is quite favorable. This would indicate the need for special public health work among the people of foreign origin.

According to the authors quoted, "the superior vitality of the native stock is fully demonstrated as to both sexes; but the superiority of the males is more striking than that of the females. The presence of the foreign stock has therefore had the undoubted effect of increasing the total death rate in New York and Pennsylvania, especially after the age forty-five is attained."

OCCUPATION AND TUBERCULOSIS

INDUSTRIAL diseases may be due to certain occupational hazards inherent in the particular industry, to failure on the part of the employer to provide satisfactory health and sanitary conditions in the factory, to physical weakness, improper food, faulty personal habits of the worker, or to certain environmental factors surrounding the industry, such as malaria, water and soil pollution, and hookworm infection. The mitigation of these existing ills depends upon the employer, the employee, the physician, and the state.

Tuberculosis as an industrial disease may be due to

one or all of these factors, and varying emphasis has been placed on one or another of these causes. Air, vitiated by dust, the products of respiration, combustion, and decomposition, the presence of toxic fumes and gases, operations encouraging postural deformities, exposure to dampness, extremes of heat and cold, sudden changes in temperature, and exposure to industrial poisons, all contribute to respiratory diseases.

Dusty occupations play a part in causing pulmonary tuberculosis. Hoffman's studies on the mortality from tuberculosis in dusty trades indicate that not all dusts are equally harmful. "It is generally admitted," says Oliver,[1] "that all dust, unless it is soluble and chemically harmless, will, if inhaled, injure the delicate structure of the lung. Some kinds of dust, such as pure silica, may cause permanent injury to the lungs, whereas coal dust—notably coal and shale dust— may cause no cumulative injury unless inhaled in large quantities. . . . Some physicians hold that fine coal dust is not destructive but may be really healthful to the lungs in consequence of the small amount of calcium present in the dust."

Nieszytka, quoted by Kober,[2] reports that 76.5 per cent of all deaths among sandstone workers in Hanover are caused by tuberculosis and, according to Grabb, tuberculosis in limestone workers is the cause of death in only 7.5 per cent of the total mortality.

Wide variations in tuberculosis mortality in occupations exposed to similar dusts can be observed from Hoffman's original tabulation. While 25 per cent of all deaths among street car conductors and motormen, and 33 per cent of all deaths among coachmen are due to tuberculosis, only 12.9 per cent of deaths among street cleaners are due to tuberculosis; the proportionate mortality from pulmonary tuberculosis is 22.1 per cent in knitting mill employes against 49.2 in lace weavers; 23.3 per cent in bakers and 36.1 per cent in cigar makers. From these figures it is evident that factors other than dust are to be considered in explaining the tuberculosis mortality. Kober concludes that "exposure to dust alone does not account for the undue prevalence of tuberculosis in certain occupations, and that every factor which undermines the general health of the individual is at least equal if not of greater importance in determining the course of the disease."

Placing the occupations not according to exposure to the different varieties of dust, but in an ascending scale according to percentage distribution of pulmonary tuberculosis, Kober explains the position of each occupation in the scale, giving the possible influence of physique, standard of living, the effects of alcohol, lead, mercury, and other industrial poisons, and the proportion of other causes of death. For example, a low rate from tuberculosis may mean there is an unusually high rate from accidents, or some other cause. The high percentage of deaths due to violence among steam railway employes, lumbermen, and raftsmen, miners, and quarrymen is responsible for their low percentage from tuberculosis.

Kober's tables indicate that tuberculosis is infrequent in occupations involving outdoor life combined with muscular activity; but it also shows that it is infrequent among bankers, officials, and hotel keepers—presumably because of the higher standard of living. The percentage in saloon keepers is 15.5, hotel keepers 9.3, and bartenders 26 per cent, showing clearly the rôle of chronic alcoholism as a cause of tuberculosis. Carpenters and cabinet makers exposed to various dusts have a percentage as low as commercial travelers; but the latter have a higher percentage from digestive diseases, indicating lower state of nutrition. The high rates for draymen, hackmen, and teamsters may be attributed to exposure to weather; but they also have high rates for alcoholism. In Great Britain the percentage in private coachmen is much lower, probably because of better habits and living conditions. The percentage in clerks and sales women is 38.7, as compared with 15.8 in salesmen.

Improvement in personal hygiene and general sanitation will offer the best safeguard against tuberculosis, according to Kober. "When we supply our children with healthful school rooms and teach them the value of pure air, sanitary homes, proper and sufficient food, physical culture, baths, and suitable clothing, and the importance of pure clean lives, the lessons taught will be applied in the homes and workshops in the nation."

THE DELRAY HEALTH DISTRICT

PROPOSED changes in the Delray health district in charge of the Detroit Health Department provide for the establishment of baby and prenatal clinics, apart from the health center, in order to make these clinics more accessible to the mothers of the district. It has been found impractical to locate such clinics at the geographical center of the district. It is claimed that a single health center building to serve the entire district is unsatisfactory. "The most feasible arrangement," according to George T. Palmer,[1] epidemiologist, "is to have a central office readily accessible from all parts of the district, which will serve as headquarters for the field nurses. In this building there will also be a tuberculosis clinic and a general diagnostic clinic. The object of the diagnostic clinic will be to reveal correctable ills and direct people to the proper agencies for treatment."

The Delray health district has been in operation since last October and cares for about one hundred thousand people, covering an area of over six square miles. An interesting observation from the influenza-pneumonia statistics given out by the Health Department shows that the proportion of reported cases was just as high in the Delray health district, containing many foreign born residents, as it was in a section of the city occupied by middle class native Americans.

SCHOOL FEEDING AND MALNUTRITION

School feeding is given a lesser rôle for dealing with defective nutrition than the one ascribed to it in earlier days, according to John C. Gebhart, in the August issue of the *American Journal of Public Health*, but it is one of strategic importance. The school lunch must be made the center from which radiate the various activities dealing with the child's nutrition.

Nothing is gained if at the end of periods of special feeding the child lapses back into its former state. The factors which determine the child's nutrition are indissolubly linked up with the home environment and the standard of living of the family, which makes it imperative to combine group instruction in food and health habits with periodical visits to the home to secure the interest and cooperation of the parents. The planning of meals with a maximum food value at a minimum cost promotes a better appreciation of the entire nutrition program.

DOCTORS AND HEALTH LECTURES

By FLORENCE L. MEREDITH, M.D.

DOCTORS do not talk enough, either to individuals or to groups, and in failing to do so are holding back the health of the public to a marked degree.

Since the war began there has been a great change in the general attitude toward health and disease. Only the fit were able to be of use to their country and an honor to themselves. Girls who went into industrial life and business life found that their opportunities for advancement were sharply limited, even the holding of their positions precarious, unless they were well. Out of about ten thousand examinations during the period of the war, made on girls in industry and business, it was found by us that only about 5 per cent were really in as good health as was possible for them. Not that all the rest were really ill—only about 10 per cent, in fact—but they were much less well than every human being has a right to be, or than is the duty of every human being to try to be. At that time the public began to feel that there is something not quite right about its general health, and began to manifest interest in the problem of how to improve it. It is time now to keep this tide of interest in health rolling on in the right direction until people are as proud of their health as in the past they have been, especially women, of their ailments.

THE URGE TO PROGRESS

Whatever is generally conceived as a proper objective tends to become possible of achievement. Nothing will serve to daunt an effort that has as its motive this popular urge.

The pity is that such irresistible impulse is not back of more movements of moment. To the fact that people have been left in uncharted ways in health matters may be ascribed the success of charlatanism in medicine and healing cults in religion.

The only rational basis of action is enlightenment, and the right source for such a program is through the ethical physician, willing to back with sound knowledge an effectual enthusiasm for health.

Health Sanctions from Physicians

The people naturally turn, that is, most of them still continue to do so, to the members of the medical profession for the health they are seeking. If it can be shown by doctors that there is any way whatsoever that this health which is becoming so popular can be achieved, it is certain that they will at least listen to what the doctors say; and a large number of them are in the mood not only to listen, but to try almost anything which comes to them with any authority back of it.

Fortunately, it so happens that science has advanced to the extent that there is a great deal for doctors to say on this subject. Some few of them are saying it, but the vast proportion are sticking to the old established method of maintaining a "professional" silence on health subjects, both in the office and in public. It would hardly seem either professional or ethical, when people are almost literally clamoring at one's door for some advice as to the ways of getting and keeping well, steadily to ignore their health education until they fail in their self-directed search and illness comes upon them. There are many theories about the maintenance of health which have become established facts—facts which the public should have at its disposal; and yet we daily find, even in the city of New York, that most enlightened of all cities, an appalling ignorance of these same facts.

If there were plenty of doctors with plenty of time and money, the ideal would of course be talking to individuals. I think it was Richard Cabot who first advocated taking the patient into one's confidence, and thus horrified physicians everywhere at the thought of dropping off the mantle of mystery hitherto associated with the wonder-workings of the medical profession. Some rightly objected that the patient would not understand what was told him and would be made worse by half knowledge. However, that all depends on what is told him. He should be told only what he can understand and what will help him. I have seen pathetic results from trying to enlighten a patient on a pathological condition, but never any ill effects from a clear, simple explanation of the why and wherefore of health.

Group Teaching of Health

But since at present there are not enough doctors to wage a constructive health campaign in the life of each individual, and since all individuals do not place themselves in a position to get personal advice, we must resort to lectures given to groups—the last thing the average physician would choose to do; but to refuse any longer will be to deprive the public of what it ought to have. It is possible that those who care for talking and can do it, might be permanently retained by states and organizations for this purpose, as they are now employed for lecturing on certain limited aspects of individual and public health, notably venereal disease. Provided these physicians still retain some clinical contact with individuals and do not become solely lecturers, such an arrangement would appear to be very satisfactory. It would not, however, exempt the average doctor from his duty to give the groups of individuals with whom he comes in contact more than they are in the habit of receiving from him, since he understands them and their needs better than anybody else. There should be available to groups everywhere more or less continuous series of lectures on health. It is an inexhaustible subject; the demand is commensurate with it already in many places, and can be made so everywhere. Every town where I have lectured has been famished for lack of such lectures, even New York, although the leaders of some of the groups were not aware of it.

The natural field for such lectures is groups as they naturally are found in factories, stores, clubs, unions, church organizations and the like. The advantage of already formed groups is that they are more likely to consist of individuals somewhat alike in their needs, although this is not always the case. All sorts of ages and varieties and occupations may be represented in one small factory. Most physicians have some such group in their care and can give them collectively far more than it is possible to give them as individuals.

The group spirit can be utilized to advantage in stimulating an interest in good habits which one person alone might be interested in only with difficulty, *i. e.*, gymnasium

exercise and sports. Group teaching has at least this one advantage over individual teaching, that it infuses a spirit sometimes impossible to arouse in individuals singly.

Two Reasonable Aims

There are two types of lecture, the purely *inspirational* one, and that formerly called instructive, but now more aptly called *educational*. The former will have to be utilized very largely further to stimulate the partially awakened hope for health, and to instigate attempts on the part of the individual to achieve it in his own life. The other type is to be used as follow-up after such an interest has been aroused, and as supplementary to medical work already under way. Our mistakes in the past in dealing with groups by means of lectures have been chiefly that we tried to give too much and too detailed information; too little educational inspiration was offered toward health and too little practical advice. In my early experience, when scheduled to talk on health, I was in the habit of giving a series of exhaustive and perhaps exhausting talks on how to live, with many dogmatic rules about health. The average individual listening to such a talk about hygiene, carefully excludes himself from any application of what he hears, as he sees himself and his neighbor apparently getting on fairly well without ever having applied these rules. Or if, perchance, he does not feel quite fit, he usually has his own theory of what ails him which such platitudes have failed to shake.

Formerly in a single lecture I tried to condense as many of the important points as possible. Now I make a single lecture or an introductory lecture an effort to show the necessity and desirability and possibility of health, what good health really is, and the folly of idly putting up with any discomfort or pain or lack of vitality without at least finding out through a complete physical examination what the cause of the trouble is, what to do about it, and then doing it, whether the alternative be medical or surgical treatment or getting better habits of living, the latter being by far the commonest need. I try to show how large a part of ill health or lack of health is due to small things which can be perfectly well corrected or avoided, provided the intelligence and the character are such as to make any sort of achievement possible. In any lack of health there is either something wrong, needing treatment, or there is nothing wrong but habits of life. We have here to exclude the inevitable effects of heredity and environment, but, fortunately, they are not always inevitable and can often be mitigated. In the former case, the advice is to undergo the treatment and get rid of the trouble; in the latter case, it is essential to find out what habits are wrong and correct them and enter into the joy of living. The stimulus toward health is the first essential in any lecture on the subject.

Scientific discussion of pathological conditions, and the imparting of a great amount of un-utilizable knowledge are to be avoided. Pathological conditions should be mentioned only to give the hearer the zeal and the knowledge of how to avoid them. But even this point of view is less constructive than giving them positive health as an aim. Moreover, if the emphasis is on ill health rather than on health, all sorts of phobias may be aroused which will naturally make the health worse rather than better as a result of a well intentioned lecture. I remember talking to a young woman who had been to a public lecture on the "ear" in which Ménière's disease was described so well and vividly that for months her mind had been so centered on the workings of her semicircular canals that she almost thought herself into ill health. *Confidence in the certainty of health provided health laws are kept should be bred in the individual—not its opposite, a fear of disease if its laws are broken.*

That health is a matter in the individual's own hands to a very large degree, and not half so much as we think is dependent on heredity or environment or the doctor, is an important point to bring out. It is also important to show that those who persistently put the blame and the responsibility entirely on someone or something other than their own habits will never reach the peak of joy and efficiency in their own maximum of health. Whatever can be invoked to fire the individual with a high aim and a strong purpose very much needs to be said.

Single Lectures or Series

If there is to be only one lecture, very little specific advice is given, the individual being recommended to seek the aid of his own physician. If there are other lectures, it has seemed advisable—and has been demonstrated as practical—to try and give a general view of the working of the body; how energy is taken in in the form of food, air, and water; what processes it goes through in the body; how energy is utilized in work and exercise and play; how the waste is disposed of; and how energy is recuperated in rest and sleep. Very often the individual hearer will come to the conclusion while listening to such an outline of physiology that his body is a wonderful thing and needs more thoughtful care. Sometimes he comes to definite conclusions as to ways he can improve his habits. Sometimes he decides to talk the matter over with his family physician and have an examination, which is what he should do.

The only rules given are those recognized as being scientifically applicable to the vast proportion of individuals not ill. The effort is not directed toward making individuals think themselves able to conduct their lives entirely alone to the best interest of their health on the knowledge that can be given them in a series of lectures. It should be understood that the lecturer is not contradicting anything the family physician may have said or may say in connection with any individual case; that he is giving principles generally desirable to live by, but subject to many variations. Many who are in fairly good health will get enough from such lectures that they will be able thereby to remedy some of their faulty habits and live at their best. For those who are not well the main aim of the lectures should be to stimulate them to want to understand their own health through conferences with their own physicians.

Provided we have interested our hearers enough in the question of health that they have followed the advice to consult their doctors, it is to be hoped that their expectation of a serious consideration of their health problems will not be lacking. Feeling not quite up to the mark and being laughingly told after a little percussion and auscultation—sometimes not even that—that they are all right, is not going to satisfy a person who has been told that there is something everyone can do to make his health better and more secure. Too many, however, needing neither medicine or surgery, are given nothing at all to help them, perhaps gain a false sense of security that they are on the right track, to harm them. It should be just as much a disgrace for a physician to fail to give advice in such a case as it is for him to be careless in the use of drugs. Unfortunately, advice is not in the same category, legally, as are drugs.

It may be argued that it will be a long time before people will feel that they can afford any consultation with a doctor unless they are absolutely in need of it. For those who can afford it at all it will probably be more

economical of money, and certainly more economical of health, to attend to any lack of perfect health early, while it is a relatively simple matter to set it right. For those who cannot afford a private physician there should be hospital service, including examination and health advice,[1] just as there is now for the treatment of sickness. We should first see that money spent in the care of the health before it is lost actually proves an advantage of the spender of the money by giving him what he is paying for,—health education. He will then not hesitate to invest. Think of the millions that are spent annually for patent medicines, a large proportion of which are taken by those who are not really ill but feel that their health needs "building up." The sum so expended has been estimated to average several dollars a year a person. The same amount of money invested in health education provided by qualified physicians would lead to results so much better that the improvement in national health can scarcely be surmised. It seems to me that we are not urging an impossibility when we suggest periodic examination and practical advice on habits for each individual in the country.

A Part of the Necessary Service

In cases were individual follow-up of the usual type of medical work is easily possible, as it would be in the case of industrial physicians, such medical service should be the main point of the lectures. But there are many things which industrial physicians say to individuals over and over again, many times a day, which could be said to large groups with considerable economy of time and effort. When the cases come through pretty rapidly, as industrial examinations are now done,[2] it is almost impossible to give any reasons for the suggestions made or, indeed, to give all the suggestions one might if time were allowed for this valuable work. Nothing will ever supersede personal discussion based on a physical examination. But lectures can be advantageously utilized to cover the whole field for the individuals collectively. In addition to the groups already under medical care, but not yet supplied with lectures, there are those groups which have no medical care at all, such as factories and stores employing no doctors, or only nurses. Women's clubs, church organizations, and forums could do no better than to offer their audiences health lectures in place of some of the good old standbys of less practical value and also of less general interest. Culture, not spelled with a K, should certainly include at top of the list, Health Culture.

The prime necessity, if the work is to be educational, is that no rules be given without reasons. In fact, it is desirable to give reasons and let the hearers formulate the rules themselves. This method is education, not instruction, which makes all the difference in the world in the future application of the newly acquired knowledge.

Arguments Against Health Work

Three objections have been raised to the idea of more lectures on health. The first is that the public will learn to do without doctors in private practice if every organization and group supplies its members with health education. It is the same objection that was originally raised against any industrial medical work and the argument has been entirely refuted. Health lectures will not have this effect any more than will any other kind of medical work. Furthermore, as the individuals will be advised to visit their own doctors for any further advice they may need—and it should be emphasized that most of them do need it—the probability is that more patients than ever, only an increasing proportion of early cases, will be seen by general practitioners, family physicians, and also by specialists.

The second objection is just the reverse of the first, that both industrial and outside physicians will be swamped with patients who are not urgently in need of care, to the detriment of those who are. But, as I have indicated, the doctors will probably ultimately find themselves with nearly the same number of patients as usual because fewer of them would become ill, and some of the others would learn how to get along intelligently without needing medical advice so often.

The third objection is that so much talk about health is going to make people into health cranks. This depends, of course, very largely on the attitude of the physicians to whom they listen. It is as possible for people to take a normal, sane interest in looking out for their bodies and conducting their physical lives as it is for them to take a normal, sane view of business problems to which they must give considerable attention, without losing their balance about it. Many people know the ins and outs of their automobile or the machine they run in the factory, who have no idea at all about the running of their bodies—an analogy which is old but ever new. It should not make a normal person disturbed to be given an idea of that most remarkable machine of all, his own body. To be sure, many people do become morbidly absorbed in the contemplation of their own mysterious "works," but it is usually from lack of a real understanding of them and not from too great an understanding. What they do not understand they are more likely to worry about. Modern methods of psychology have proved this. A little knowledge is a dangerous thing, if given in any number of possible wrong ways and wrong times to wrong people; but the right sort of physician can make neurotic people less so rather than more so by judicious information.

I have seen girls who, while mystified about physiological processes, were morbidly concerned about them, but who could give these facts their proper weight and value when their significance was understood. Thus, with the danger in mind of the possibility of making health cranks, it can surely be avoided. Even if one appears here and there, a system should not be condemned which is for the greatest good of by far the greatest number. They are, moreover, less likely to become abnormal in this respect if they are on the hygienic régime which would logically follow health education than they would be if they waited until real ill health is established before taking a close interest in their bodies, at which time they are almost sure to become cranks if there has been any initial tendency in that direction.

It is doubtful whether too much attention can ever be given to the question of health except in the few cases in which it becomes a sort of worship of health, resulting in making the individual not a crank, but self-centered. I have seen girls made intensely selfish for a time, disregarding any and all other obligations in looking out for their own physical good; but, when they ultimately realized that their self-development was not the only end to be gained, in order to become a sort of Nietschian super-woman, but that they may also fulfill better their obligations as a part of a great whole, then came an appreciation of the fact that the need of one's health may sometimes clash with still more urgent needs, and must for a time perhaps be definitely set aside. Living in trenches, for example, could hardly be called ideally healthful; yet a greater thing than health of the indi-

2. Meredith, Florence, M.D.: Physical Examinations, Jour. of Industrial Hygiene, February, 1920.

vidual was thereby achieved for the race, and often for the individual as well. But these departures from the path of health must always be deliberately understood ones, and the path must be resumed as soon as it can with honor.

Arguments Against Health Lectures

To sum up, the function of group teaching, which is necessary in order to cover the field of health education more completely than can now be done by individual methods, is first to stimulate, then to educate. Those who do not believe that this can be done are not familiar with the signs of the times. We have thought that the public could be interested in its public health by being forced into it by boards of health. We have thought that the public could not be interested in its personal health because there was no force to compel him. We have ignored the possibility of making his own desire for comfort and happiness and efficiency a greater force than any external compulsion. Pressure of circumstances has already partly done this. The rest of the task is one for physicians to undertake. One way physicians can do this is to utilize in every case he sees a broad scientific knowledge of the subject of health; and to demonstrate his belief in the possibility of much better health resulting from much better habits; and to feel, himself, a great enthusiasm for the full, complete living which is made possible only if the health is right. This is, of course, better done in private consultations; but because it cannot be quite so well done with groups is no excuse for not doing what is possible in that way, provided the importance of the personal consultation is not minimized. The lecture certainly offers a too important way of teaching health to be any longer neglected.

HEALTH AND THE RURAL SCHOOL

By LOUIS WIN RAPEER, Ph.D., President, Research University, and LOIS M. CHRISTENSEN, A.B., War Department, Washington, D. C.

THAT people who live in the country are healthy seems to be taken for granted by many. Such expressions as "back to nature" and, in reference to city dwellers who may be persistently afflicted with some bodily ailment, "You should get out into the country for a while," are indications of this general idea. It seems only natural, as indeed it should, that, with floods of sunshine, unobstructed breezes, foods fresh from their natural sources, and bodily exercise a part of each day's program, the human creature placed in the Garden of Eden to have dominion over all, should fall but little short of perfection.

Facts Measured by Theory

It will prove interesting to give a little consideration to the facts and see how they measure up to the theory. Various reasons have made it desirable to ascertain with some degree of accuracy the health conditions of rural communities, comparatively much more difficult to determine than similar facts for urban populations, where citizens and their activities are to a considerable extent classified and regulated for the good of all. Nearly every one has some conception, however vague, of the congested districts of large cities where the ignorant and unfortunate are crowded together in dark and unventilated habitations and in streets whose atmosphere is forever fetid with the odors of decaying food and refuse of every description. Here it is that those born in poverty and those reduced to poverty from a more fortunate state find refuge, poverty leading to ill health, and ill health in turn increasing poverty. One expects the statistician to report a high death rate under such conditions, and the expectation is not disappointed. So deeply have the unfavorable aspects of city life impressed themselves upon many minds as to give rise to the expression, "God made the country but the devil made the city."

But the country, where more than half of the people of our nation still live, is free from the handicaps to which the poor in cities are subjected. There the people have air and sunshine, fresh food, and opportunity for healthful exercise. Those broken in spirit and feeble in health do not take refuge in the country; neither does the poor and ignorant foreigner, his body and mind affected by the oppressions of Old World tyrannies, seek an asylum in the open fields of our free land. Beyond doubt, the rural community is free from many menaces to health against which cities, especially large cities, must contend.

However, a study of health statistics may only give further proof of the accepted truth that the greater the task the greater the incentive to accomplish it, with the consequent development of the necessary efficiency. In a special study of rural sanitation, begun in the spring of 1914 by the United States Public Health Service, some very significant and surprising facts were brought out. In the census year of 1900, of the total number of deaths the percentage resulting from typhoid fever was 3.75 in the rural districts and but 1.78 in cities. In 1915, from twenty-five states from which figures were tabulated, it was found that in cities with a population of 10,000 or over, the death rate per 100,000 averaged 13.7; while in rural districts, including towns of less than 10,000 population, the rate was 13.6. Although it is most gratifying to find from statistics that the death rate from typhoid fever in the United States has been reduced at least 50 per cent, it must be noted that this is largely, if not entirely due to sanitary progress in the larger cities. From facts gained by intensive and extensive study of health conditions throughout our country it becomes evident that the rural community has problems which have not yet received the deserved attention of its own members nor the Government as a whole.

Investigation has shown that in view of its natural advantages the rural community does not enjoy the blessing of health in a degree that might reasonably be expected. Our next consideration must be to discover the causes. The death rate is governed largely by communicable diseases, of which typhoid fever is one of the most prevalent, and the extent of which can usually be taken as an index of sanitary conditions in a community. Its prevention serves at the same time to prevent many other diseases, such as hookworm, dysentery, and summer diarrheas of infants. Widespread understanding, then, of the manner and means by which these disease germs are communicated will be necessary in order to prevent the contagion. Fundamentally, in the spread of disease the germ

must pass from an infected person to others, who thus also become infected. The various means by which this transfer may take place must be considered in order to provide adequately against the diffusion of the germs.

How Infections Are Carried

Obviously, the waste matter and impurities, of which disease germs are the most virulent form, are being constantly eliminated from every living body. This is accomplished in three ways: through the pores of the skin, the exhalation from the lungs, to which might be added discharging of infectious secretions of the nasal passages and throat, and the excreta from the alimentary canal. By the same sign, through any of these channels a healthy body may become inoculated with disease germs. To guard against the spread of communicable diseases, which in general means the preservation of health, these three gateways must be guarded. The pores must be kept open and clean by adequate bathing and careful avoidance of contact with clothing or towels that have recently been used by a possibly infected person. No disease germ should be permitted to enter by nose or mouth. There must be regular and copious breathing of pure air which vitalizes the blood, while at the same time affording an opportunity to discharge from the lungs the impurities which they have filtered out from the blood. Since for most communicable diseases the principal mode of spread is by droplets of saliva containing germs thrown out in breathing, care must be taken that the inhalation is not contaminated by the breath of others. Finally, the natural sewage system of the body must be kept to the highest degree of efficiency and the waste and germs so disposed of that they cannot possibly infect other persons.

If germs were transmitted by personal contact only the problem would be comparatively simple. When, however, it is considered that the great germ carriers are flies, mosquitoes, and other insects, as well as rats, mice, cats, dogs, or other animals, it becomes evident at once that control of all these lines of communication involves no small task.

In view of these considerations, it is not so hard to understand that rural health conditions are not all that might be desired and that scientific, systematic treatment is essential here as in all other human affairs if anything like success is to be attained. As already indicated, sanitation in the larger cities has made wonderful progress, because it was an accepted truth that living conditions are artificial—which, by the way, is not a term of reproach—and that changed conditions must be met with corresponding precautions and safeguards.

In rural communities the original, and too often the succeeding inhabitant, relied too largely on natural resources and could not or would not see the necessity of complying with the fundamental laws of life, especially when the health of his or his neighbor's family was concerned. The basic idea of "living in the country" was to wrest from the soil, first a living, a competence; then, perchance, wealth. All other considerations were subservient to this. It must be conceded that at first, unaided, the struggle was not an easy one, and appealed only to the more hardy and those with simple, quiet tastes and few desires. With the one central purpose, it is not so strange that other considerations, those which perhaps we might call the more humane considerations, were treated as of little importance. To wrest its treasures from the virgin soil was the primary object; anything that was conducive to this end, anything that represented the attainment of this purpose, was worthy of thought and care. The battle was to the strong.

Hence it is that one need not feel surprised to find on the domain of the more successful farmer well filled barns and stables of the most substantial and convenient kind, farm machinery of the most efficient and modern make, and even automobiles of the latest and most pretentious models, while among the livestock—horses, cattle, hogs, poultry—the best of breeds are found. At the same time we may find a sickly wife and untrained or half-trained daughters trying in an uncertain way to make a home in a house not half so good as the barn; where no one has had time to think of screening all the doors and windows in the summer time; where a complete bathroom, which would not cost half so much as the automobile and would have done fifty times as much good, is an impossibility.

The same comparative valuations can be detected in the great majority of homes of the less affluent, down through all grades. The rural condition is a state of mind. To increase the value and productivity of the soil and its accessories—that has been the one great purpose. The intrinsic value of the human element has not been sufficiently considered and, in ignoring the claims of the higher nature, man has here, as not infrequently elsewhere, suffered also a material loss.

Must Introduce New Ideas

How the rural school can be used as a medium for the introduction of new ideas and habits that shall revolutionize the mode of living and bring to the community the health which it is ideally supposed to have, is a question worthy of serious consideration. Its unique position as a connecting link between the local, personal interest of the community and the commonwealth, of which the community is a unit, makes it the natural channel for the enlightenment which must precede any material changes. State and national organizations are created and financed to study conditions, to make careful analyses of their findings, and to recommend remedies for whatever they find detrimental or injurious; but, in a large measure, it remains with the community to adopt or neglect such recommendations. If county and state authorities were in control of the sanitary conditions of rural communities even to the extent that they exercise control over the academic requirements of the public school teacher, the process of improvement would be more simple and direct. But with so little vested authority, the problem remains largely one of popular education.

First, then, the rural citizen must be awakened to the fact that he and his are not enjoying the blessing of health which might be attained so easily. In this, one of the simplest and most effective incentives to human effort can readily be applied—the awakening of the spirit of rivalry. In the heart of every country man there is a smouldering grudge against his city cousins, a latent suspicion that he is looked down upon because of his crude and simple manners and his ignorance of the sciences and appliances that make city life so attractive. If he can be led to desire that which he should have, the battle is half won. Medicine administered in the form of candy is often as efficacious as that offered and taken "because it will cure."

In the effort to eliminate insanitary conditions and promote every activity that would be conducive to the well being of the community, a judiciously applied suggestion of "the way they do it in the city" often meets with a ready response. For example, let the rural teacher exhibit to her school pictures that appear from time to time of New York school children being instructed in the proper manner of using a tooth brush. In this con-

nection the occasion can be used to explain the fundamental purpose and need of this bit of personal sanitation. The fact that a great deal of sickness is caused by germs that originate in the mouth may be emphasized. To this practical presentation of the facts there may be added by the way the little remark that it is sometimes said that "there are two kinds of people, those who brush their teeth and those who do not." The combined appeal to practical advantage and personal pride will sometimes work wonders.

In the study of hygiene or such general presentation of the subject as the limited curriculum of the rural school permits, instead of bestowing such painstaking care to impress upon the minds of the pupils the fact that in the human skeleton there are two hundred six bones, with the name and number of each, the really human teacher, with a love of life that overflows in a desire to see her pupils developing in accordance with the laws of nature which she is supposed to teach, will find many opportunities to present lessons of vital importance to their physical betterment. The effect of improperly cooked or insufficiently masticated food will be explained. The very great factor that physical health becomes in ultimate success of any kind will be pointed out and dwelt upon, giving, perhaps, such examples as Theodore Roosevelt and Robert Louis Stevenson, the first of whom started the battle of life with a brilliant mind and a weak constitution and who literally built up a vigorous physique by systematic care and exercise, and the latter of whom by as carefully and systematically measuring his food and daily tasks, prolonged his life of usefulness far beyond that which would otherwise have been possible.

In innumerable ways incident to the teaching of the prescribed subjects the wise teacher can inspire her pupils with a desire for personal excellence and wholesomeness that will open the way for the many material reforms so badly needed in many rural communities. Laws and public regulations are good and cannot be dispensed with; but in our America, if nowhere else, we cannot, nor do we wish to, depart from the fundamental idea that our government must be by the will of the governed. To enlist that will, then, in the cause of improvement is the logical means of progress. While teaching the children, and through them the community in general, that health is a thing greatly to be desired, as necessary condition for the full enjoyment of life as well as a source and foundation of the power that every normal human being covets, practical lessons in its attainment can be given. Having pointed out that even a sickly child may build himself into a robust man, that it all depends upon how the game is played, it will not be hard to keep up a real interest in such things as breathing properly and keeping the various muscles of the body in trim by appropriate exercise.

Which Type Shall Dominate?

While convincing the farmer folk that the most valuable crop that is growing is the crop of boys and girls, the future men and women, who may easily dominate the affairs of our country if they so will, specific lessons in hygiene and sanitation may be given. With the growth of self-respect, that is, the realization of one's personal worth, there comes a carefulness that is not otherwise found, a care for one's self and likewise a care for one's neighbor. For instance, among the less experienced and oftentimes diffident country children, in contrast with the easy self-possession of the great numbers of children in city schools, there is a marked tendency toward communism, as in wearing one another's hats or clothing, using the same towel or even handkerchief, and drinking from the same cup—all of which practices are fraught with many dangers to the health of the individual and the community. As the desire for health and the avoidance of infection becomes a habit of mind as well as a matter of understanding, the insanitary result of flies, bad odors, personal uncleanliness, and the like, will be given a more effective consideration.

To an extent that makes it a subject worthy of serious thought there is a real ignorance of the causes of sickness which often gives rise to harmful superstitions on the part of many people, affecting even some who are comparatively intelligent. There seems to be in the human heart an inherent tendency to attribute to the gods whatever is not understood. That sickness and death have too often been regarded as "dispensations of Providence" against which no struggle should be made, is indicated by such expressions as "everyone has to go when his time comes," such resignation being declared, when to the enlightened it is perfectly evident that disease and death were the result of contaminated drinking water or failure properly to dispose of sewage, garbage, and other infected accumulations.

It would be time well spent in teaching history, to dwell upon some of the awful scourges and epidemics, and make it clear that almost countless lives could have been saved but for the ignorance of the causes of the disease and the unclean habits of the people. The lessons should be made absolutely clear and practical by calling attention to the fact that the same or similar conditions may or even do exist in that very community, even though easily remediable. If at all possible, actual illustrations should be made, as, for example, by analyzing polluted water or presenting an illustrated scientific description of such analysis, together with the results of experiments with such disease germs. This can also be applied to other means of infection, such as milk improperly handled or from diseased cows, or the handling of clothing or other articles that have been recently in contact with diseased persons.

As a suggestion in regard to means by which the rural school in the person of the teacher may contribute toward making the community a health resort, there might be diffused a more illuminating interpretation of the motto of our country, *"E pluribus unum"*; it might be applied to that very community by showing how each farm may have all the sovereign rights of a central gov- that each and all are benefited by having a central government, even with highly paid officials, each to give his undivided efforts to solving a specific class of problems for the good of all. It might then become apparent that it would be an economy rather than expense to pay a worthwhile salary to a county health officer, to employ an examining physician who would make a periodic examination of every child and prescribe proper treatment, or even make possible the treatment at public expense if necessary to protect the health of the community. The traveling automobile clinic is yet to be adopted in rural districts.

Is the rural school teacher to work a miracle, and accomplish such a stupendous undertaking in addition to her prescribed duties? As a momentary digression, it might be suggested that much of the present routine work might as well be dispensed with, since it is fruitless. Perfunctory progress from the first to the last page of a text book written for city children may accomplish no worthy object except it be the cultivation of book-reading persistence. In the book that some of us still

revere we may read, "The letter killeth but the Spirit giveth life," and another expression of the same thought, "As a man *thinketh* in his heart so is he." Are the daily lessons such as will lead the pupils to think, in solving vital problems facing country people? Are not many precious hours wasted in wearisome performance of that which has little meaning or purpose? A "spelling book" of the old type is an atrocious thing, little short of a crime. But shall not a child learn to spell? Certainly, the words that he uses in letter writing, but not from stupid, stupefying lists of words. The "dictionary habit," added to the ability to spell a "minimal-essential" list of two thousand words, will make a spelling book unnecessary. How many of us can look back upon our childhood days and remember that because of its strange combination of letters which somehow would not keep properly adjusted in our plastic brains the word "catarrh" was assigned as a punishment, or otherwise, to be written "fifty" or "one hundred" times? It was written—mechanically, of course,—and possibly by the very monotony of repetition the letters and their proper sequence were finally impressed sufficiently to remain; but, while the process was going on, the young body, equally susceptible with the mind, was afflicted with a constant "cold"; there were frequent coughing, persistent irritation of the throat and nasal passages, which developed in later life into chronic "catarrh" whose spelling might have been learned if needed, almost incidentally if attention of children and parents had been directed to the condition instead of the word, and their understanding enlightened as to the disastrous effects and applicable means of prevention.

Schools a Factor in Welfare

Is it in any way possible so to conduct the rural school that it shall be a strong factor in the welfare and development of the community, physically as well as mentally? Some suggestion has been made as to what could and should be done, but how can it become certain that these services will not be dependent upon the wisdom and devotion of the individual teacher? How can modern science and the practical, helpful application of it be brought to the rural community? Here as elsewhere, real and lasting success can come only through concerted action, through effective cooperation. Isolated efforts are apt to be lost, and the good seed sown fails to develop through lack of care. The small district school with its one teacher, in one room, and under the direction of a school board composed of men usually of no educational experience and with little time to devote to their honorary office, cannot, or, at least does not, produce satisfactory results. The teacher, however competent and courageous, needs assistance and support. With the best of understanding and intentions the efforts of the individual teacher in the small school district must be inadequate.

The consolidated rural school seems to be the only solution of this highly important problem. The uniting of interests and combining of funds would make it possible to secure the supervisory service of a medical man whose approval would lend weight to the daily teaching as well as provide superior knowledge whenever it might be necessary. On the larger scale of building the school could be provided with proper sanitary conveniences which would fulfill the threefold purpose of safeguarding the health of the children during school hours, serving as a practical demonstration, and, not least important, "forming the habit" of correct living. Interest born of cooperation and strengthened by the prospect of attainment would bring about a more effective consideration of the local needs. The school should be made the community welfare service center for the practical enlightenment of adults as well as of the children. Where ignorance, stagnation, and disease existed in the isolated community, the consolidated school with its larger powers for adequate and sustained effort, could develop a general and concerted interest in the physical welfare of the people[1] which could not fail to result in greatly improved sanitary conditions in the homes and environs, and in the habits of personal carefulness, which would go far toward giving to country life the ideal healthfulness that it is supposed to possess.

[1]Rapeer. The Consolidated Rural School, Scribners.

OKLAHOMA CITY HEALTH SURVEY

Other American cities might take some suggestions from the public health survey of Oklahoma City, Okla. An analysis of the city budget, submitted in the report of the public health survey recently completed by the Oklahoma Tuberculosis Association, and reported by Murray P. Harwood, of the Massachusetts Institute of Technology, and Jules Schevitz, secretary of the Association, affords a description of conditions in municipal affairs that challenges the attention of officials and citizens.

The assertion is made by the Central Committee for the Oklahoma City Public Health Survey that the *per capita* appropriation for protecting the public health is only two-fifths of the minimum amount of money which should be appropriated for health work. The expenditures of the health and city chemist departments for the years 1915, 1916, and 1917 were, respectively, $0.21, $0.18, and $0.20, *per capita*, although it has been estimated by the American Public Health Association that adequate health protection for a community, under pre-war conditions, required an appropriation of about $0.50 *per capita*.

Oklahoma City does not have a full-time health officer. The authors recommend that the city reorganize its Health Department with a full time, well trained health officer as the chief executive of the new department. He should be appointed under civil service.

The plan provides for the establishment of a diagnostic laboratory and the appointment of a bacteriologist who will not only have charge of the laboratory, but will serve as assistant health officer.

The present city chemist would be retained in the same position and would conduct all chemical analyses in connection with the laboratory work of the health department.

The scheme of reorganization contemplates the revision of the sanitary and milk codes so that a model sanitary law will be put into effect, and enforced through the cooperation and aid of qualified citizens of the community. A thoroughly trained milk inspector would be employed under the supervision of the health officer.

The appointment would be made of three sanitary inspectors who would look after the conditions in food markets, stores, restaurants and lodging houses, and general housing. Protection against infection and contagious disease carriers with respect to the handling of foods in stores and restaurants is inadequate under the present inspection, according to the authors.

The survey brought out the need of a better record of vital statistics of Oklahoma City. When birth registration was checked up it was found that the death rate and birth rate are about one-half of the rates that prevailed in cities having more accurate statistics. Cases of

contagion and the diseases of children are poorly reported. It is urged that the model vital statistics law adopted by the state be made the guide in the reporting of vital statistics.

The extension of the facilities of municipal sanitation is urged for the improvement of sections where suitable

A row of beautiful homes, typical of Oklahoma City.

improvements have not been made. It is recommended that the supervision and regulation of housing facilities from the standpoint of health, comfort, and convenience of the people, shall be carried out by more frequent inspections and by education.

Of sewerage and sewage disposal the report states: "On the whole, the city is well sewered, although there are still certain sections where open privies abound. contains a fairly large amount of organic trade wastes which are particularly offensive during warm weather. No method of sewage treatment is employed."

Toilet facilities in use at one of the outlying schools of Oklahoma City. These privies are not properly protected against flies.

Oklahoma City lacks an adequate supply of water from the municipal reservoirs. The water works and system came into the possession of the city in 1900. The city has grown to the extent that a larger supply must be provided. To offset the deficiencies of the municipal water supply, a large proportion of the city's drinking water supply comes from wells operated by private corporations. The survey included these wells in the facilities for handling and distributing the water.

A chapter is devoted to anti-tuberculosis activities. In 1917 the death rate of 200.9 in 100,000 represented the mortality rate of all forms of tuberculosis among the black population as compared to 69.5 in 100,000 among the white population. The high mortality among the negroes is entirely out of proportion to the color distribution of the population. They make up 10.2 per cent of the city's population although they contribute about 25 per cent to the deaths of tuberculosis. The unusually high death rate among negroes from tuberculosis is attributed party to their peculiar racial susceptibility and partly to the poor conditions under which they live. An analysis of the possible contributory factors to the prevalence of tuberculosis in Oklahoma City does not lead to any definite conclusions.

Conditions under which the city's milk supply is obtained are described as follows:

"The milk supply of the city comes from a short distance. The milk in most cases is brought to the city twice a day. Forty-four dairies were scored, and of these 31 per cent scored less than 60 per cent. The distributing dairies and ice cream companies within the city were also inspected. Many one and two cow dairies

The type of drinking can used in all the public schools. Individual drinking cups are not provided, and many children drink directly from the faucets.

located in the city create a special problem. Those that handle milk and other foods are not required to undergo a thorough medical examination in order to determine whether they are free from disease."

Oklahoma City has resolutely looked her health facts in the face and a consistent health program is planned as the outcome.

A few "shacks" on South Robinson Avenue, where dangerous housing evils prevail. Unprotected garbage swarms with flies, and rubbish lies unremoved.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

INTERNATIONAL CLINICS. Edited by H. R. M. Landis, M.D., Philadelphia. Volume II, Thirteenth Series, 1920.[1]

The present volume contains many interesting papers. The article on tuberculosis of the bone and joint diseases by Ashhurst, and the paper on occlusion of the arteries of the limbs in diphtheria, by Thompson, are especially well written.

Two new departments have been added to this volume of International Clinics; one is the department of industrial medicine, and the other is the department of pediatrics. Both sections contain unusually good material and they demonstrate the growing importance of both phases of medical science, an importance that the editor was not slow to cite.

PRINCIPLES OF HUMAN PHYSIOLOGY. By Ernest H. Starling, C.M.G., F.R.S., M.D., Hon. Bc.D. (Cambridge and Dublin), F.R.C.P. Jodrell professor of physiology in University College, London.[2]

Professor Starling's book is rendered particularly valuable by his method of approach to the subject under discussion. He always describes the structure of the organ before he discusses its physiology. For instance, he starts with a full description of the structure of the voluntary muscle before he presents the general subject of the mechanism of movement. In the same way he gives a description of the structure of the nerve fibers before he enters upon a discussion of the physiology of the nervous system.

He follows the same methods in regard to the chemical structure of various reactions. The book thus becomes a cyclopedia of anatomical, physiological and chemical knowledge, showing the interrelation between these branches of medicine and their connection with the functions of the human organs.

The third edition includes many of the newer researches on physiology and also a valuable contribution on sense organs by H. Hartridge.

DIAGNOSTIC METHODS. Chemical, Bacteriological and Microscopical. A Text Book for Students and Practitioners. By Ralph W. Webster, M.D., Ph.D., assistant professor of pharmacological therapeutics and instructor in medicine in Rush Medical College, University of Chicago; director of Chicago Laboratory, clinical and analytical.[3]

The sixth edition of this standard book brings all the laboratory methods up to the last minute. It gives full descriptions of all clinical laboratory methods and in many cases also the interpretation of the findings. The bibliography is exceptionally complete. The volume can render inestimable service to both the clinician and the laboratory worker.

3. P. Blakiston's Son & Co., Philadelphia, 1920.

THE USE OF COLLOIDS IN HEALTH AND DISEASE. By Alfred B. Searle. With Foreword by Sir Malcolm Morris, K.C.V.O.[4]

This book on colloids by Searle gives excellent and apparently comprehensive information of a fundamental nature concerning this subject. The portion which deals with the chemistry and physics of colloids is easily grasped by one who has had not more than the usual college course in chemistry. The style is clear and interesting and, as it is a small book, if one starts reading the book will not be put down until it is finished.

The subject is a most important one and the fundamentals, at least, should be known to every physician. Biological processes and metabolism are to a great extent those of colloidal substances. As these substances act in an entirely different manner from that of simpler substances the field of colloid chemistry is a very important one and deserves more time and investigation than has been given it in the past.

It is unfortunate that the chapter which deals with the therapeutic value of colloids does not maintain the high standard of the remainder of the book. The book as a whole, however, is worthy of very serious consideration.

THE INDIVIDUAL DELINQUENT. A Textbook of Diagnosis and Prognosis for all Concerned in Understanding Offenders. By William Healy, A.B., M.D., director of the Psychopathic Institute, Juvenile Court, Chicago; associate professor mental and nervous diseases, Chicago Polyclinic.[5]

The book of Dr. Healy is a most painstaking analysis of specific types of delinquents with the object of attaining a grouping or classification which will enable a practical handling of these types of offenders. The data tabulated cover the family history, development history, environment, mental and moral development, anthropometry, medical examination, particularly from a neurologic and psychiatric standpoint, psychological tests and analyses, delinquency, and diagnostic and prognostic summary.

Emotional complexes and rationalizations are regarded as more important than the nervous functions which have engaged most psychologists in this field.

He does not find poverty a very important factor in the causation of crime. Mental abnormalities and peculiarities were found in 455 of 823 classified offenders.

In 271 out of 668 cases he was able to eliminate hereditary criminalistic tendencies. In 152 cases of undoubted mental defect the inheritance of criminal tendency as such could not be proved from the facts. The intricacy of causation calls for the most painstaking study.

The case studies are minute and exhaustive. It is only through such methods that criminalistic genetics will evolve as an exact science.

HEBE

—a wholesome, nutritious, economical food product for cooking, baking and hot beverages

Helps to Balance the Diet

THE great value of HEBE as a food lies in the perfect balance of its ingredients. HEBE is pure skimmed milk evaporated to double strength enriched with cocoanut fat. It supplies to the diet the proteins, carbohydrates and mineral salts of skimmed milk plus the heat and energy units of a highly refined vegetable fat.

Used as a cooking ingredient in the preparation of other foods, HEBE adds nutritive value, and helps to balance the diet. There is no other article just exactly like HEBE—it has its own special uses—serving as an auxiliary to the daily milk supply for cooking, baking and for use in hot beverages.

HEBE is prepared in modern condenseries under the most sanitary conditions. It is put up in hermetically sealed cans and sterilized. It is plainly labeled: "A Compound of Evaporated Skimmed Milk and Vegetable Fat." The label recommends HEBE for cooking and baking and in hot beverages, and specifically states that it is not to be used in place of milk for infant feeding. It is just as frankly advertised and sold.

Our booklets, "Today's Food Problem" and "HEBE—Its Dietetic and Economic Value," are of special interest to physicians, health officials, dietitians, public health and industrial nurses. Both will be sent free on request. Address 3022 Consumers Building, Chicago.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

Book Reviews

(Continued from page 706)

TRANSACTIONS OF THE AMERICAN PEDIATRIC SOCIETY. Thirty-first Session, Held at the Chalfonte Hotel, Atlantic City, N. J., June 16, 17 and 18, 1919. Edited by Oscar M. Schloss.[6]

The Transactions contain all the scientific papers read before the American Pediatric Society during its annual convention in 1919, and a report of the business transacted at the meeting. It also contains a list of the presidents of the society and its members. The volume is well edited and well bound.

THE TREATMENT OF SYPHILIS. By H. Sheridan Baketel, A.M., M.D.[7]

This little volume really fills a long felt want. It is a laboratory manual for the man who treats syphilis. It is concise and readable, yet contains all the essentials of modern anti-luetic therapy. It gives concise instruction in technic, the various steps being illustrated by a series of excellent photographs.

Laboratory tests for diagnosis are taken up briefly. A chapter is devoted to the chemistry of anti-luetics, principally arsenic, which may be somewhat technical, yet it is only by having some conception of their complex chemical nature and instability that we can understand the necessity of exercising the most scrupulous care in their preparation and administration. Another valuable chapter is the one dealing with the reactions and accidents following the use of arsphenamine. Intraspinal administration is also treated rather thoroughly.

A MANUAL OF PHYSICAL DIAGNOSIS. Austin Flint, M.D., LL.D. Eighth edition, revised by Henry C. Thacher, M.S., M.D.[8]

Thacher states in the preface of this book that medical teachers are giving too much laboratory and too much technical instruction at the expense of those physical signs ascertainable by the senses. He further says that the students are asking for this. We agree that teachers are stressing too much the newer diagnostic methods, but it has been our experience that the students "eat up" a clinic in which the fingers, the eyes, and other senses are the only diagnostic means employed to demonstrate physical findings. That is the reason we believe this book should have a real place in the student's library; because the treatment of diagnosis is throughout sensibly considered, conclusions are well balanced, and the subject is presented in an ideal manner for a medical student. We are particularly pleased with the discussion on pulmonary tuberculosis and heart murmurs.

SIR WILLIAM OSLER, Bart. Brief Tributes to His Personality, Influence, and Public Service. Written by His Friends, Associates, and Former Pupils, in Honor of His Seventieth Birthday, and First Published in the Bulletin of the Johns Hopkins Hospital for July, 1919.[9]

This book has already been completely reviewed in another column of this journal when its contents first appeared in the *Bulletin of the Johns Hopkins Hospital* of July, 1919. To this review we will add the statement that the little volume should become a part of every physician's library. Personally, we believe that in later years this book will have all the value of a rare first edition.

From the Frying Pan Into the Consulting Room

IT IS becoming increasingly manifest that improperly selected food, and improperly cooked food may be the specific causes of all sorts of under-oxydation disorders — such as nephritis, diabetes, rheumatism, blood pressure changes, indigestion, malnutrition and anemia.

Professor William H. Porter, in his new book, "Eating to Live Long," in discussing the question of what bad food does to good health, says:

"Animal fats have a low burning point. If used at a temperature that would adequately cook the meat, fish, or other food, they proclaim to the entire neighborhod just what the family is going to have for dinner—to say nothing of the fact that the meat being prepared is rendered almost indigestible by its protracted seance in the frying pan.

"If broiling is not practicable, it is possible, through the use of corn oil—or some oil capable of being heated to 600° or more before the burning point is reached—to greatly help in taking the teeth out of the frying pan, and at the same time serve to make the food more palatable and digestible."

Mazola is used now by more than seven million housewives in all cooking, baking, frying and sautéing—and also as a pure salad oil, quite as good, in the opinion of many connoisseurs, as the very finest imported Italian Olive Oil.

Suggest to your patients, Doctor, that they try Mazola while they are under your care, and see what a difference it will make in them.

Chicago Club Open to Visiting Nurses

The Chicago Nurses Club has a beautifully furnished club room overlooking the lake. The room will be available for nurses' meetings and conferences. Out of town nurses are urged to visit the club when in Chicago.

Central Council Moves Offices

The Central Council for Nursing Education and the Central Branch Office of the National Organization for Public Health Nursing have moved to the fifteenth floor of the Lake View Building, 116 South Michigan avenue, Chicago. They will share offices with the Chicago Nurses Directory and the Chicago Nurses Club.

MASSACHUSETTS UNITES SANATORIUMS

The state tuberculosis sanatoriums of Massachusetts, which were formerly under the supervision of the Board of Trustees of Massachusetts Hospitals for Consumptives, have been placed under the Department of Public Health, forming a new Division of Sanatoriums. Dr. William J. Gallivan has been appointed director of this division.

CHICAGO SCHOOL FOR SAFETY SUPERVISORS

The Safety Council of the Chicago Association of Commerce, operating in conjunction with the National Safety Council, is holding on alternate Tuesday evenings, commencing September 14 and concluding on March 29, 1921, a school for safety supervisor designed to give practical, readily understood instruction in "safety with a minimum expenditure of time and effort." Safety is fundamentally a humanitarian work of conserving life and limb, but it has a tremendous economic value as well and it is hoped, says the Chicago Council, through this school to send out men who will become leaders in safety.

CHILD SUICIDE INCREASING

Suicide is generally on the increase in the United States, and especially among women and children there is an alarmingly larger number who have ended their lives, says the *American School Board Journal* in commenting on data accumulated by the Save-a-Life League. During the first six months of 1919 the League received reports of 2,063 suicides throughout the country; this year for the corresponding period the number of those who have destroyed themselves is 2,771. Male suicides were 1,810 and female 961. In 1919 there were 385 suicides in New York during the first six months. This year the total is 343—234 men and 109 women. Of this number, nearly two-thirds were between the ages of twenty-five and fifty, and twelve were under twenty-one. Quoting the report, the comment runs:

Nothing should cause more real alarm than the suicide of children. In our own country, with its boasted institutions for human betterment, during the last six months 88 boys and 137 girls committed suicide, an increase of 50 over last year's report for the same time. The average age of boys is sixteen and girls fifteen. Boys most frequently use a gun and girls take poison. These terrible facts urgently call for strictly enforced laws to suppress the sale of all poisons and firearms.

There is a noticeable increase of suicide among women, doubtless due to the fact that women today are entering upon public life as never before, both in business and in politics. Not long ago about one-fourth of all suicides were women; now it is one-third.

Many people begrudge the Time the right kind of Sleep requires

THE day's work is pressing. Every man has about twice as much on hand as he ought to be asked to do.

Few people sleep long enough, or soundly enough. Many begrudge the time the right kind of sleep requires. Others who do get their full night's sleep fail to be benefited by it. They do not properly relax. Their bed squeaks and rattles. They devote the proper length of time to sleep but, somehow, they are restless, disturbed, sleepless—

As a result, they start the day only half rested, are inefficient and dissatisfied with their work and accomplish little. "Sleep" to them becomes "almost a waste of time."

Nobody can sleep deeply and be fully benefited by their sleep unless he or she is completely relaxed—unless the bed *invites* sleep instead of repelling it.

No bed that rattles and squeaks with every turn of the sleeper can be expected to make "sleep" anything else but "a waste of time."

For over forty years Simmons Company has been making beds and springs that *invite* sleep—

Beds that stand true and staunch; that lock firm at the corners, each part rigid, secure and in perfect alignment; beds that are noiseless, comfortable, sanitary, serviceable, and enduring.

Simmons Beds, "*Built for Sleep*" cost no more than perfect beds ought to cost—no more than anybody who values comfort and health will be fully prepared to pay.

The quiet elegance, simplicity and refinement of their design, their superior construction and the certainty with which they encourage sleep, make them essential to the health, comfort and efficiency of the people.

Special Data and descriptive booklets of Simmons Beds for Hospitals, Schools and Outdoor Recreation Camps, will be mailed promptly on request.

PUBLIC HEALTH LAW IN COSTA RICA

A new public health law has been adopted in Costa Rica, placing all public health matters in charge of the national government, which will exert its powers through the local authorities. A superior board of health will administer the law, which deals specifically with the various public health subjects.

VITAL STATISTICS IN SPAIN

The *Siglo médico* states that 306,394 boys were born in Spain during 1919, and 278,958 girl babies, to a population of 20,355,986. Over 842,000 deaths were recorded, including 163,198 children under five. Typhoid was responsible for 5,677 deaths; typhus for 228; tuberculosis for 29,700; cancer for 12,525; heart disease for 37,883; acute bronchitis for 22,166; chronic bronchitis for 11,705; suicide for 847, and other forms of violence for 6,909.

A DIMINISHING PROFESSION

The American Red Cross sees in the widening disparity between the increase of our population and the decrease in the number of graduates from medical institutions an added reason for promoting general training in first aid and accident prevention.

The present standard of pre-medical education has lengthened the time and increased the cost of medical training, thus curtailing to a large extent the yearly attendance at the medical colleges. In 1904 there were 28,142 students attending the various medical colleges of the United States, this being the largest number in any year during the period 1880-1919. The total number of medical students in the schools for the year ending June, 1919, excluding pre-medical, special and post-graduate students, was 13,052. There was a decrease in 1919 of 578 below that of 1918.

The high standard of efficiency established through the reclassification of medical colleges has caused the closing of many of the smaller and more poorly equipped ones. In 1906 there were 162 medical colleges in the United States; in 1919 there were only eighty-five recognized medical colleges. In 1903 there were 5,698 graduates from all medical colleges, one graduate for every 14,020 of population. This number has gradually declined, in spite of the increase in population, until, in 1919, there were only 2,656 graduates, a decrease of fourteen below that of 1918—one graduate for each 40,230 people.

The longer hours and smaller remuneration of country practice have caused many physicians to move from the rural districts to the larger towns, where conditions are less difficult and remuneration greater. Many practitioners, desiring to specialize also, are attracted to the cities from the rural districts.

That the high standard of medical education must be maintained goes without saying, if we are to render efficient service to those suffering with disease. Nevertheless, the shortage of practitioners has caused increased suffering in certain localities which is very severely felt. Those who reside in the sparsely settled areas are left to the care of untrained assistance, and serious illness or loss of life often results.

Universal first aid training would supplement the work of the physicians, and take from them the burden of caring for unimportant injuries. It would release their services for more serious cases, and would also place the victims of accidents in the physician's hands in the best possible condition for future recovery.

LISTERS PREPARED CASEIN DIABETIC FLOUR

for DIABETES

ABSOLUTELY STARCHLESS and SUGARLESS

ANALYSIS

Moisture	10.66
Ash	1.63
Fat	0.67
Protein	69.95
STARCH	0.00
SUGAR	0.00
Leavening and Flavoring	17.09

LISTERS Diabetic Flour is made by our own original, exclusive process. Blended of specially prepared caseins; contains no purins; entirely free from starches and sugars. About 95% is assimilated and 90% goes into energy.

SELF-RISING—Extraordinarily versatile. Easily made into strictly non-carbohydrate Diabetic Bread, Cookies, Muffins, Biscuits, Noodles, Pancakes, Dumplings, French Toast, etc. —delectable to both the eye and the palate; nourishing; healthful; and of very great value in breaking up the depressing monotony of the usual Diabetic diet.

Packed in small, carefully measured boxes

—each containing just enough flour to make one loaf of Diabetic Bread—the right amount per day for the average patient. In this respect, alone, of wonderful assistance to both physician and patient in the strict regulation of the Diabetic diet.

A Month's supply—30 boxes $4.85
Fifteen Days' supply—15 boxes 2.75

Will be sent direct to the physician or to his patient. Or write to us for name of our Agent in your locality

Electrically Lighted Surgical Instruments

Twenty years in the manufacture of electrically lighted surgical instruments, if it has not brought perfection in instrument construction, at least has kept the Electro Surgical Instrument Company abreast of the advances made by leading specialists of the medical and surgical profession.

So it is that instruments stamped "E. S. I. Co." speak of the accomplishments of the noted men whose suggestions are embodied in their construction and a service of maintenance possible only in instruments of our manufacture.

Users of instruments stamped "E. S. I. Co." are certain sharers in this service.

Origination begets imitation. Be sure of our exact name.

CANADIAN TUBERCULOSIS CONSULTANTS

The Board of Tuberculosis Consultants appointed by the Department of Soldier Civil Re-Establishment for Canada are. Charles D. Parfitt, M.B., Gravenhurst; J. R. Byers, M.B., Quebec; W. M. Hart, M.B., Saskatchewan; A. F. Millar, M.B., Nova Scotia; and N. A. Stewart, M.B., Manitoba.

REPORTED CURE OF LEPROSY

The newspapers made a good story of the reported cure of two patients from the leper colony at Penikese, Mass. An inquiry elicited the information from Bernard W. Carey, M.D., director, Division of Communicable Diseases, that the men in question have exhibited a remarkable improvement and show no external evidences of the disease. While in the opinion of the Board these men are progressing toward a complete cure, and are not now a menace to public health, they have been returned to the island until all laboratory and blood tests remain negative.

TRAINING HEALTH OFFICERS IN GERMANY

The plan for training health officers will soon be realized in Germany, says the *Deutsche Medizinische Wochenschrift*. Social hygiene academies have been organized at Breslau, Berlin, and Dusseldorf and four months courses are to open with the winter term to train district and communal physicians, medical inspectors of schools, and in medical prophylaxis work in general. The various branches of study include social hygiene on the basis of social economics, medical statistics, and social pedagogics; social pathology; care of the healthy and care of the sick, embracing prevention and stamping out of epidemics; social legislation, insurance medicine, and medical ethics. The instruction will be on the plan of graduate schools with the main stress on practical training. Physicians who wish to compete for positions as *kreisärzte* will find facilities for a course in bacteriology and hygiene; jurisprudence, and legal psychiatry. Certificates from these academies will entitle to precedence among applicants for positions as health officers, city physicians, and medical inspectors of schools.

AN ALL AMERICAN HEALTH CONFERENCE

The first of a series of regional health conferences authorized by the International Health Conference in Cannes is to be held in Washington, December 6-13. It will be devoted to a consideration of venereal diseases which, according to conservative estimates, constitute one of the world's most terrible plagues.

The conference is being organized under the joint auspices of the United States Interdepartmental Social Hygiene Board, the United States Public Health Service, the American Red Cross and the American Social Hygiene Association. Prof. William H. Welch of Johns Hopkins Hospital has consented to serve as president, and already assurances have been received that some of the foremost physicians and sociologists will participate. Prominent health officers and sociologists from all parts of North and South America will attend.

The conference will review past experiences and existing knowledge as to the causes, treatment and prevention of venereal diseases, and will formulate recommendations relating to a practicable three-year program for each of the North and South American countries participating. In addition it will make suggestions for putting such programs into effect.

The Efficiency of Our Employees

Is Reflected in

The Efficiency of Our Product

Scientific apparatus represents more than a combination of material and labor. The interested, efficient, and intelligent cooperation of the workers is needed to produce efficient apparatus.

We have secured such cooperation.

We pay a bonus on production—we penalize defective workmanship.

The man who will not earn a bonus is not wanted. Every employee is an efficiency engineer.

With such support from our organization, the production of QUALITY apparatus is a natural sequence.

Let us tell you about the QUALITY in

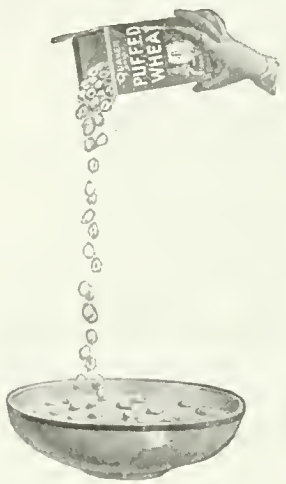
100 Million Explosions

In a Grain of Wheat



Puffed Wheat is whole wheat steam exploded. The grains are sealed in guns. After an hour of fearful heat the guns are shot. And over 100 million steam explosions are caused in every kernel.

The process was invented by Prof. A. P. Anderson, to make whole grains wholly digestible, and easy to digest.

Puffed Rice is whole rice puffed in like way. Corn Puffs are corn hearts puffed.

These bubble grains, flimsy and nut-like, form most delicious foods. And they are the best-cooked cereals in existence.

Puffed Wheat
Puffed Rice
Corn Puffs

COLORADO HEALTH COURSE

The University of Colorado School of Medicine announces a four months course in public health nursing—September 20, 1920, to January 8, 1921—to be conducted under the auspices of the University at the Minnequa Steel Works and Hospitals. The field work in mining camps and in Pueblo provides facilities for industrial nursing and social service among the thousands of workers and their families.

RISKS INVOLVED IN KITCHEN REGIME

The possibilities of food infection by a carrier have received further emphasis in the report of Dr. Joseph Priestly, medical officer at Lambeth (England) on an outbreak affecting ten persons who had partaken of food prepared by a woman who, though ill of the same disease that later affected all the members of the household, continued to prepare their food. The food itself was sound, but bacilli of the large paratyphoid B group were carried in the gravy and were found present in the organs of the deceased and in the blood of those who survived. In the case followed by death, verdict was brought in that death was caused by "gastro-enteritis by food-poisoning misadventure." Heretofore rigid proof had not been found that the Gaertner group of infections, the cause of food poisoning outbreaks, are of human origin, the food being infected with pathogenic Gaertner bacilli from a human source, either from an actual case of paratyphoid fever or a carrier case. The subject has been ably summarized by Dr. William B. Savage in his recent volume on "Food Poisoning and Food Infection."

RACIAL PROBLEMS AND MODERN CRUSADES

The real welfare of a race is represented by a combination of factors not too well understood even by those who are attempting to apply correctives, says Robert B. Wild, in *The Lancet* of July 3, 1920, in an evaluation of some modern health crusades. Without making any attack upon these crusades, he suggests that it is important to consider their racial as well as their individual effects. It is well in the long run, he says, to concentrate effort upon those diseases which destroy the individual in early adolescence rather than the diseases which remove men when their powers are on the wane. It would, for instance, have more value to be able to eliminate tomorrow the tubercle bacillus, a disease which exacts a high toll among the young, than to control cancer, a disease of later middle life, or arteriosclerosis, the control of which permit greater numbers to go on through a slow process of senile decay.

Venereal disease, affecting, general speaking, those individuals whose passions are strongest and moral control weakest, takes its toll from those of the race who leave fewer offspring and these less likely to reach a healthy maturity.

Dr. Wild does not look for much gain from the cultivation of eugenics, but considers that probably our present methods of sexual selection give as good results as would be obtained by a more conscious and deliberate method.

The matter of drug addiction is more complex and needs to be the subject of special study and concentrated toward control, but in all of the problems which face the medical profession at the time he urges the necessity for taking a broad and unsentimental view of the issues. If in the future the work of the medical man is to be held more preventive than curative he will have to think more of the community and of the race than he has done in the past without thinking less of the individual.

Ariston Flavoring Extracts

Test higher in purity and strength than is required by the Pure Food laws. They are made in a fully equipped laboratory by thorough and careful methods.

Only the finest quality of vanilla beans, bunches of which are shown in the upper part of this border, is used in making Ariston Vanilla Extract. They are chopped fine, put into barrels, where they remain in maceration for many months, to allow the alcohol to extract the essence, which becomes rich and mellow in character, with a delicate flavor. It is then drawn off and drips through the percolators ready for bottling.

One Corner of Our Extract Laboratory.

Besides Vanilla, we make all flavors, including Vanilla-Tonka, Orange, Almond, Lemon, Peppermint, Wintergreen, Clover, Celery, Nutmeg, Sassafras, Anise, Onion, and others.

You can rely on our extracts as being pure and wholesome and the best that can be produced.

"DEALERS DIRECT WITH YOU"

DIPHTHERIA ANTITOXIN

Shown by Tests to Cause Least Reaction

In a series of comparative tests conducted by the John McCormick Institute for Infectious Diseases, covering 370 cases and extending over a period of 2½ years, our product—which is manufactured under the personal supervision of P. G. Heineman—gave only 3% of slight and moderate (but no severe) serum reactions.

"Since the antitoxin has been administered in a solution of almost pure globulin prepared by Heineman's method, the occurrence of serum reactions has markedly fallen, not only in frequency but also in severity." (Medical Report of the Durand Hospital of the John McCormick Institute for Infectious Diseases—March 12, 1913 to March 12, 1918.)

Our laboratories are producing this high grade concentrated serum in sufficient quantities to ensure immediate delivery of your season's requirements.

Furnished in syringes and vials containing the standard prophylactic and therapeutic doses of from 1,000 to 20,000 units.

TROPICAL DISEASE INSTITUTE PLANNED

An effort is being made to bring about the establishment in Panama of an international institute for research on tropical diseases as a memorial to the late Major General William C. Gorgas, Surgeon General, United States Army. Panama has been chosen as a location in view of the fact that the most noteworthy health research work of General Gorgas was accomplished there. The Panama government will, it is said, donate the million dollar St. Thomas Hospital for the proposed institute, and it is hoped that the Rockefeller Foundation, which did so much to rid Panama of hookworm, will cooperate in this enterprise.

PROVISION OF MEDICAL TREATMENT

The primary necessity in getting effective improvement in medical service is public enlightenment, states Dr. A. H. Bygott, in *The Lancet* of August 14, 1920. The people would be much more likely to seek assistance early if educated in the knowledge of the incidence of disease so that a doctor would be consulted when certain signs, which may lead to serious consequences, first appear.

The chief emphasis of Dr. Bygott's argument is placed upon the provisions of convenient consultation rooms with proper equipment for adequate examinations. The hospital is regarded too little as the center of the medical life of the community, he says, and hospital records do not supply the exact and reliable information they should regarding the incidence and methods of dealing with disease. It would be reasonable to require, he says, that each hospital should publish "statistics of the nature of the work done, so that the public may know how it fulfills its function as the main source of supply of the highest forms of medical service in the locality."

A long waiting list should be a disgrace, he adds, and in such cases precedence is not always assured to the urgent case.

Remedies are suggested in the staffing of hospitals, in the training of men, and in making available for public benefit the best skill of the surgeon in the interval before he becomes subject to the overpressure that makes for an irregularity which interferes with the patient and is not conducive to just class work. When senior surgeons must see their patients hurriedly and lack the leisure for comparing their work with others, their work might well be supplemented by help from the staff of a teaching hospital.

An interesting and successful experiment enthusiastically favored by the British Medical Association in West Suffolk is reported of sending out a distinguished consulting surgeon for local services. A double purpose could be served by choosing such consultants from the staff of teaching hospitals. This local consultation service is available to those who cannot travel and would equalize the work by preventing the overcrowding of institutions in large centers by consultative cases from distant districts.

A survey of all the hospitals would enable a strengthening of the staffs of the lesser hospitals, adequate service in rural and industrial districts, of visiting specialists, and a distribution of service according to need. The social clinical man should have the advantage of serving on the hospital staff so as to centralize all service and standards everywhere raised by providing a central information bureau in a consultative capacity on matters of plans, organizations and personnel.

The nutrient value of VIROL illustrated in a number of cases, particulars of which have been supplied by medical men.

After being fed on VIROL regularly for five months he is a fine, strong, healthy boy. The Doctor says:—"I have pleasure in confirming the statement of the wonderful improvement made by this child after feeding on VIROL. I feared his case was hopeless."

Maurice Pickering was suffering from blood poisoning. His lungs were also affected. He wasted worse than he appears in above photograph.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

Virol is a valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars:
50c, $1.00 and $2.00

CONCENTRATED FOOD—A well-known medical man writes as follows: "I have never prescribed a better tissue builder than VIROL and I have been in active general practice for over forty years."

The fat in VIROL is so minutely divided that it is more readily absorbed than milk.

TUBERCULOSIS RATE IN SASKATCHEWAN

Tuberculosis continues to claim lives in Saskatchewan at an increasing rate. In 1914 the death rate was 35.2 per 100,000; in 1915, 38.2; in 1916, 44.6; 1917, 47.4; 1918, 54.5; making the average for the five-year period, 45. The average for measles was 6.2; whooping cough, 8.2; diphtheria, 8.2; typhoid, 8.8.

HEALTH PROBE OF SCHOOL CHILDREN

An appeal to parents to support the White William Foundation in its efforts to secure better physical efficiency among the school children of Philadelphia is urged by Dr. Edwin B. Twitmeyer, psychologist to the University of Pennsylvania. From 10 to 15 per cent more of the school children, he says, would be promoted if they had an examination before entering school in September. The school nurses' report for the year ending June 30 showed that 5,911 cases of badly diseased tonsils were discovered during the year by medical examiners.

POST-GRADUATE LECTURES IN OHIO

The Committee on Medical Education of the Ohio State Association for some years, in a series of group meetings throughout the state, has conducted lectures designed to bring to the medical men of the state the newest developments in medicine. Announcement is made in the September issue of the *Ohio State Medical Journal* that Dr. Henry John Gerstenberger, professor of pediatrics, Western Reserve University, is this season's lecturer. Every year a larger number of physicians who find it impossible to leave their practices for further study avail themselves of this opportunity to keep themselves *en rapport* with current medical thought. The work is twofold, one section dealing with the fundamentals of pediatrics, the other with the newer developments of practical importance to the family physician. The topics cover thoroughly the specialty from the standpoint of prevention, diagnosis, and treatment.

LABOR FEDERATION APPROVES HEALTH INSURANCE

The New York State Federation of Labor has approved the principle of health insurance in the following resolutions, adopted by the Executive Council under date of May 14, 1920:

Whereas, The long-neglected sickness problem of the wage earners is now receiving marked attention in the various states as a result of the agitation for workmen's health insurance legislation, and

Whereas, The facts gathered by official commissions, as well as recommendations following their impartial studies, have been in the majority of instances overwhelmingly in favor of this legislation, and more than fifty state and national trade union organizations in the United States have endorsed it, and

Whereas, Continued discussion of the subject, preparatory to the enactment of health insurance laws, has already disclosed to public attention and condemnation selfish opposition of commercial and insurance interests which have long opposed adequate workmen's accident compensation and sickness insurance laws, be it

RESOLVED, That the Executive Council of the New York State Federation of Labor redouble its efforts in support of health insurance legislation in conformity with the recommendations of its annual conventions, and invite the cooperation of other organizations in thus promoting the health of the people.

INTERNATIONAL TUBERCULOSIS CONFERENCE

The National Tuberculosis Association has announced from its headquarters at 381 Fourth Avenue, New York City, an International Conference on Tuberculosis held in Paris the week of October 7, 1920. The last International Conference on Tuberculosis was held in Rome in 1912. Leon Bourgeois, president of the Council of the League of Nations, presided.

NORTH CAROLINA LEADS SOUTH

During the year from June, 1919, to July, 1920, 5,505 women and girls completed courses in home hygiene and care of the sick given by the Southern Division of the American Red Cross. In this work North Carolina led with 736 students taking the full course, and 581 taking the modified course. Tennessee came next with 567 taking the complete course and 309 the modified course.

MISSISSIPPI VALLEY ASSOCIATION OFFICERS

The Mississippi Valley Conference on Tuberculosis held at Duluth September 2-4, 1920, was attended by 335 workers. The following officers were elected: Walter McNab Miller, M.D., St. Louis, president; E. B. Pierce, M.D., Howell, Mich., vice-president; and Mr. Harry Roulfs, Columbus, O., secretary-treasurer. The meeting place selected for the next conference is Cedar Point, O., near Sandusky.

NEUROPSYCHIATRIC ASSOCIATION ORGANIZED

The Ontario Neuropsychiatric Association has been organized with the following officers: Dr. Edward Ryan, Kingston, president; Dr. Harry Clare, Toronto, vice-president; Dr. C. Crawford Whitby, secretary-treasurer. The work of the Association will extend to the study of defective children, social welfare work, care in the selection of immigrants, the problems relating to the feebleminded, psychoses, and neuropsychoses.

CITY EMBARKS IN MILK BUSINESS

The city of Jamestown, N. Y., has voted an appropriation of $150,000 for the erection of a milk plant, the installation of a pasteurizing process, the buying of milk from producers, and the organizing of milk routes through the city by the municipality. This is an innovation in municipal enterprises and carries the indorsement of the Board of Health, the common councils and practically all of the physicians of the city. The plant will be under the sole direction of a commission appointed by the mayor.

ASKS AID FOR TYPHUS

Unless effective steps are immediately taken, the plague of typhus will be far more deadly in the winter of 1920-21 than it was in the winter of 1919-20, says Arthur Balfour in a letter appealing for $1,250,000 out of $150,000,000 needed to deal with the growing menace in Poland and eastern Europe. In reporting his appeal the *New York Times* quotes Mr. Balfour as addressing "all members of the family of nations" through the Council of the League of Nations. The epidemic in Poland and Galicia, he states, is becoming an international danger, and the recent military events have made more urgent the need of money to cope with it.

MODERN MEDICINE

A Monthly Magazine of Medical & Health Progress for Physicians & for Others Interested in Administrative, Industrial & Social Health Problems

Editors, ALEXANDER LAMBERT, M. D., S. S. GOLDWATER, M. D., *and* JOHN A. LAPP, LL.D.
Managing Editor, JOHN A. LAPP
Editorial and Business Offices, 22-24 EAST ONTARIO STREET, *Chicago*

Volume 2 November, 1920 Number 11

WHO SPEAKS FOR THE MEDICAL PROFESSION?

THE increasing confusion of leadership in the relation of the medical profession to the public should afford occasion for serious thought to the farsighted members of the profession at this time, when the state legislatures are about to convene. Who speaks for the medical profession? The question arises every time a bill affecting physicians appears in a legislature. The regular medical societies should be expected to be the voice of the profession on such occasions with full allowance for those who have individual views to present. Legislators and the public have a sympathetic ear for the voice of the real leaders of medicine, whether speaking as individuals or as the representatives of the regular medical societies. Such spokesmen secure results in legislative matters and promote public confidence in the medical profession.

Confusion arises when medical men appear representing medical societies which are formed for the immediate occasion, or which represent commercial elements within or without the profession. The public cannot readily distinguish between such representatives and the real representatives of medicine. Associations with high sounding names are not easily distinguishable by the laymen from the time honored professional organizations which have upheld the ideals of the profession for years. The result is that undue attention is ofttimes paid by legislatures to blatant representatives of quackery and commercialism in medicine. There lies before the writer at this moment a document which, from the title and name of the organization, would appear to a legislator to be the official voice of the physicians of a great state. At least six important medical and health measures which are generally approved by regular medical societies are roundly condemned by this document.

The public will readily understand the difference if the regular associations assume the leadership and fairly but firmly repress those who presume to speak for the physicians through special organizations created by self-seekers under specious pretenses.

MODERN MEDICINE SELECTED BY NATIONAL ASSOCIATION

THE American Association of Industrial Physicians and Surgeons at their semi-annual meeting in Milwaukee, September 28, 1920, adopted MODERN MEDICINE as the official organ of the Association. Beginning with the issue for January, 1921, the department of Health in Industry of this magazine will be under the direction of a board of editors selected by the Association and will be enlarged to meet the new responsibilities of representing the profession of industrial physicians and surgeons.

To the readers of this magazine the new arrangement offers substantial advantages. The American Association of Industrial Physicians and Surgeons is the only American organization of the new but very important profession of industrial medical men. The Organization stands for health in industry in its broadest sense and for the application of scientific medicine to that end. The contributions of the Association, through the columns of MODERN MEDICINE, will profit greatly all those who are especially interested in preventive medicine. The Association

will make the department of Health in Industry a clearing house of information, personal notes, and scientific progress.

With faith in industrial medicine and surgery as the great epochal advance in medicine of these times the editors of MODERN MEDICINE welcome this new alignment with the American Association of Industrial Physicians and Surgeons.

NATIONAL CAMPAIGNS FOR HEALTH WORK

HEALTH workers are actively interested in the progress and success of the two great national campaigns for funds and membership conducted by the American Red Cross and the National Tuberculosis Association, which culminate in the months of November and December.

These two organizations have gained a preeminence in the field of health and welfare; they have the confidence of all people regardless of station; they perform functions which merit the fullest support, and their potentialities for human welfare are almost unlimited.

These organizations are democratically supported, as befits their service. Their call is to the rank and file to whom their service is dedicated.

THE PUBLIC INTEREST IN SCIENCE

ONE of the first provisions requisite in any democratic form of government is a general educational system devised to train the citizens so as to put self-determination on a rational basis. This must be accomplished or there can be no stability of government and no means of translating into terms of general uplift the results of research or of evolving that background of definite information out of which a sound conception of progress emerges. It has not appeared necessary or desirable, however—or at least no consistent effort has been made—to disseminate the results of scientific investigation, and such information on these matters as is current among the general public is fragmentary, unrelated, and, for the most part, acquired through spectacular accounts of the Sunday newspaper. In an effort to gain some idea as to popular conceptions of the fundamental facts of psychology, the University of Iowa recently conducted an inquiry which brought out the fact that mental science is popularly linked up with the occult science and, while general notions as to the nature of dream, subconscious, and hypnotic phenomena are vague in the extreme, reading in regard to the spirit world is general and receives much more ready credence than is accorded accurately determined psychic phenomena. This popular tendency to mysticism in the absence of definite knowledge becomes of urgent importance in view of the readiness with which various religious cults engage to cure bodily as well as mental ills, and of the danger involved in transferring emotionalism into issues which should be determined only upon rational bases.

What gain is it to deny chiropractors legal sanction in the state of New York if Illinois is to be restrained from regulating them and a referendum in California proposes to license them? What does it profit to require a seven year course for physicians if any religious cult can put forth practitioners, or if so-called "systems" with no standards of education are authorized to give diplomas after a two weeks' course of lectures?

The recent statement from the Bureau of Animal Industry of the Department of Agriculture on the extent to which animals have served the public health is especially opportune for the issue in California which, again on referendum, asks the general public to decide on the merits of vivisection; but will the facts weigh out and win against this sort of opposition? The *California State Journal of Medicine* quotes a chiropractic organ as saying, "Let the legislature make its laws and the Medical Board try to enforce them. Give Me the Newspaper Space—Give Me Publicity, and they can have all else, and we will cop the verdicts of the juries."

The materials of research are not of mere academic interest. The products of scientific study should receive publicity through a semi-popular statement of the facts properly presented and persistently offered as public health education. A more rational and more wholesome concept of these matters will emerge only on knowledge acquired from impartial sources as the basis of popular decision. S. P. M.

CHILD HEALTH ORGANIZATIONS COME TOGETHER

THE coordination of the work of several important national agencies dealing with the problems of child health by the American Child Hygiene Association, the American Red Cross, the National Child Labor Committee, and the American Nursing Association is a wise step and doubtless the forerunner of other wise steps in coordinating public health activities. A properly coordinated program has been evolved after prolonged conferences, the associations engaged in the present undertaking are to be commended for the broad and constructive view of service shown by them in working more closely together for the common end.

THE NATIONAL TUBERCULOSIS ASSOCIATION: WHAT IT IS AND WHAT IT DOES*

By PHILIP P. JACOBS, Ph.D., Assistant Secretary, New York City

The National Tuberculosis Association is a shining example of the success that follows sound business methods in a health organization, and the response that may be evoked everywhere by a concrete appeal.

Just as special services are required within the distinctive field of tuberculosis work, so does the larger organization fall into its place in a larger health program. To eradicate tuberculosis involves a comprehensive campaign for public health.

Also, it emphasizes that machinery for health work becomes effective only when industry and the community consent to put their houses in order and when the individual assumes essential health habits.

IN fifteen years the National Tuberculosis Association, starting upon a shoe string, has developed an organization which in the calendar year 1920 will spend, largely in education, approximately $4,000,000. Similarly, in fifteen years the National Tuberculosis Association has stimulated the development of public and private expenditures from hardly more than $100,000 in 1905 to approximately $30,000,000 in 1920, most of which is spent for institutional, dispensary, and nursing work. In these sentences are epitomized the growth and history of the tuberculosis campaign in America.

Begins Public Health Movement

When the National Tuberculosis Association was organized in June, 1904, there was no such thing as a general tuberculosis or public health movement in the United States. The knowledge that tuberculosis is a communicable, a curable, and a controllable disease was the property of only a few savants. The great rank and file of the people were still in medieval darkness so far as tuberculosis was concerned. There were a few scattered efforts, mostly along the Atlantic seaboard, seeking to educate the people with regard to the nature and control of tuberculosis, but most of these exhibited only a feeble light and that at intermittent intervals.

At the very beginning of its career the National Tuberculosis Association wisely conceived that if its work was ever to be done rightly it must be developed by means of proper state and local anti-tuberculosis associations. With this end in view, the first efforts of the Association were directed toward a broad, extensive educational campaign the object of which was to bring to everybody a knowledge of the simple facts regarding the nature, treatment, and prevention of tuberculosis. In the second place the Association sought, on the basis of this education and on the basis of such known facts regarding the spread of tuberculosis in communities and among individuals as could be secured, to develop state and local interest in the disease. It was not long before associations began to spring up here and there in various parts of the country, and by 1908 several hundred such were in existence.

The most difficult problems that the National Tuberculosis Association had to confront in the development of these new organizations were, first of all, the providing of sufficient funds so that the associations could do a proper piece of work in their own communities; and, secondly, the providing of programs along sound lines to prevent the frittering away of the meager funds that might be secured. The alliance of the National Association with the American Red Cross in the Red Cross Christmas Seal Sale proved to be of the greatest possible service in both of these directions. The fundamental, sound conception of the leaders of the National Tuberculosis Association and the Red Cross in those early days that the bulk of the money derived from the sale of Christmas seals should remain in the community where the seals were sold, has been and still is the policy that has made the tuberculosis campaign the greatest public health movement in America.

By means of the Red Cross Christmas Seal Sale the National Tuberculosis Association was able to take a number of valuable steps forward. In the first place, in new and unorganized territory the seal sale was the best way to provide the initial funds with which to develop an infant association. So successful was this method of approach that at the present time a well organized state association with a full time secretary and a business administration is at work in every state in the Union, and by the application of this same principle on the part of state associations many of the larger local centers of population are similarly organized.

*The third of a series of articles on National health organizations prepared especially for the readers of Modern Medicine.

A second step forward, which the Red Cross Seal Sale made possible, has been the development of standard programs. The fact that the National Association was able to give or withhold the contract for the sale of seals has afforded to it the strongest possible means of bringing into line those states that would otherwise have frittered away their seal money in milk and eggs or on loose programs of little or no value to the forwarding of tuberculosis work.

The Program Standardized

In the third place, the succession of seal sales year after year has by means of the division of percentages between local, state, and the national associations brought about a solidarity in the tuberculosis campaign which it would have been difficult to achieve under any other circumstances.

A partial view of offices and library of the National Tuberculosis Association, New York. The extent and efficacy of the work are largely the result of the centralization of activities accomplished through this office.

As a result of this development of the campaign against tuberculosis under the leadership of the National Tuberculosis Association there are at the present time approximately twelve hundred state and local associations and committees for the prevention of tuberculosis in the United States. The number of sanatoriums and hospitals has developed from a hundred to nearly six hundred. The number of clinics and dispensaries has developed from nothing to more than five hundred. The number of nurses doing tuberculosis work it is impossible to estimate accurately at the present time, but as nearly as can be determined from statistics that are available there must be at least 3,000 nurses doing tuberculosis work almost exclusively and there are several thousand others doing some tuberculosis work. In 1905 there was not a single tuberculosis nurse in the United States. Of open air schools, as nearly as can be estimated at the present time, at least 2,000 schools and classes might be grouped under this head. The first institution of this sort in the United States was opened in 1908.

Besides these definite developments, there are a number of indefinite developments not so easy to catalogue. It would be interesting, for example, if one could estimate the number of sleeping porches the antituberculosis campaign has brought about in the last ten years, or how many hundreds of thousands of people have learned to open their windows, or what the effect of the tuberculosis movement has been on public spitting. The influence of the tuberculosis campaign upon the entire public health movement, in the securing of better health officers, or the provision of better laws, or in a number of other ways, cannot be tabulated in cold statistics.

As the campaign against tuberculosis has developed and as state and local associations have been formed in various parts of the country the functions and methods of the National Association have naturally changed. The staff of the Association is constantly growing and the budget has similarly expanded. The original budget of the National Association was approximately $10,000; the Association in 1920 will spend approximately $175,000.

Unifies All Workers

The Association is an organization of laymen and physicians. It is supported entirely by voluntary contributions, its support coming from three sources: (1) a percentage from the sale of Christmas seals contributed by state and local tuberculosis associations; (2) membership dues; and (3) donations. At the present time the Association has a membership of approximately four thousand. By far the largest percentage of money received for its support comes from the Christmas seal sale.

It is governed by a board of directors representing geographic and other interests involved in the campaign. The members of the Association meet once a year in annual meeting and the Board of Directors and Executive Committee from four to eight times a year.

The staff of the Association consists of salaried experts in various matters relating to tuberculosis and is organized in six different services, as follows: Administrative, field, medical, modern health crusade, research, and publicity and publications. A brief outline of the work of each service, which follows, will give a good conception of the general methods and functions of the Association.

The Administrative Service, as its name im-

plies, is responsible for handling the organization's administrative details. Under it comes the direction and coordination of the work of the various members of the staff. It is the service that also provides the contact with outside agencies and coordinates the efforts of the National Association with those of other organizations, both public and private. All of the business transactions of the Association fall under this service. Since the National Association serves as a clearing house for the purchase and distribution of many supplies dealing with tuberculosis, the financial transactions in a given year will aggregate as high as $300,000.

Field Service Closely Related

The Field Service, although closely related to the Administrative Service, is immediately responsible for carrying out the Association's policies in the field. Due to the lack of sufficient funds, it has been necessary recently to cut down the Field Service somewhat. The work is done largely by personal visits by members of the Special Field Staff. Through surveys, individual conferences, group conferences, institutes, correspondence, and in many other ways, the Field Staff keeps in touch with the various activities throughout the country. The Field Service is the organizing department of the Association.

Four Lines of Medical Service

The Medical Service has four distinct lines of work:

(1) The handling of all of the correspondence and other matters of the Association involving questions of medical detail, such as inquiries from patients regarding advice in the treatment of tuberculosis or the stimulation or promotion of medical activities in state and local associations.

(2) The promotion of medical education with particular reference to tuberculosis through state and local associations, medical schools, conferences, and in other ways.

(3) The establishing and promotion of standards for construction and maintenance of hospitals and open air schools; the study and promotion of occupational therapy; and the training and placement of arrested cases of tuberculosis. In this connection the Medical Service cooperates closely with the government agencies doing similar work.

(4) The promotion and standardization of tuberculosis nursing. The secretatry for nursing is in constant touch with the developments of nursing work, and by means of conferences, correspondence, and publication of articles, helps to promote interest in tuberculosis nursing and to coordinate the nursing activities of the tuberculosis association with those of other state and national agencies.

Modern Health Crusade Service

The Modern Health Crusade Service is in immediate charge of the Modern Health Crusade, a movement for the health education of school children. More than six million children are enrolled in the Crusade in 1920. The Crusade aims to teach health habits to children and to provide a system of health education for the public schools. This service originates new ideas for the Crusade, publishes literature dealing with the program and organization, handles supplies necessary for carrying on the work, and promotes interest in higher standards. The Crusade is probably the most popular feature of the anti-tuberculosis campaign at the present time. Every

The first efforts of the Association were directed toward a broad and extensive educational campaign with the object of bringing to everybody a knowledge of the nature, treatment, and prevention of tuberculosis.

state and most of the local associations in the country are doing Crusade work.

Conducts a Research Service

The Research Service falls into three definite lines, as follows:

(1) Study of particular problems, such as those of the indigent migratory consumptive, the economic loss from tuberculosis, the decline of the death rate, and so forth.

(2) The editing and preparation for publication of various monographs and pamphlets put out by the Association. This involves collecting of new material, such as that for the tuberculosis directory, the preparation of the transactions, and the compilation of information on new literature and new happenings for the publications of the Association.

(3) The cataloguing, filing, and indexing of the

literature, publications, and pamphlet material of the office so that it may be available for immediate study by all members of the staff and by others who are interested. The Association's library is gradually developing a complete bibliography on all of the social phases of the tuberculosis problem and on many of the medical phases.

Publicity and Publications Service

The Publicity and Publications Service carries on four different activities, as follows:

(1) The handling of publicity, particularly for newspapers, magazines, and other periodicals. Every well known method of publicity is used in this connection.

(2) The publication of three monthly journals, the *Journal of the Outdoor Life*, the *American Review of Tuberculosis*, and the monthly *Bulletin* of the National Association. The service is responsible not only for soliciting subscriptions and securing advertisements, but also for the editing of these publications. The *Journal of the Outdoor Life* is a popular lay magazine. The monthly *Bulletin* is the house organ of the National Association, and the *American Review* is the medical and scientific journal of the Association.

(3) This Service prepares material for and directs the Loan Service, which includes the loan, rental, and sale of motion pictures, lantern slides, photographs, cuts, special scrap books, etc.

(4) The direction of the Christmas Seal Campaign, membership campaigns, and other special campaigns carried on by the Association, together with the promotion of such campaigns in state and local associations, falls under this Service.

The Framingham Health Demonstration

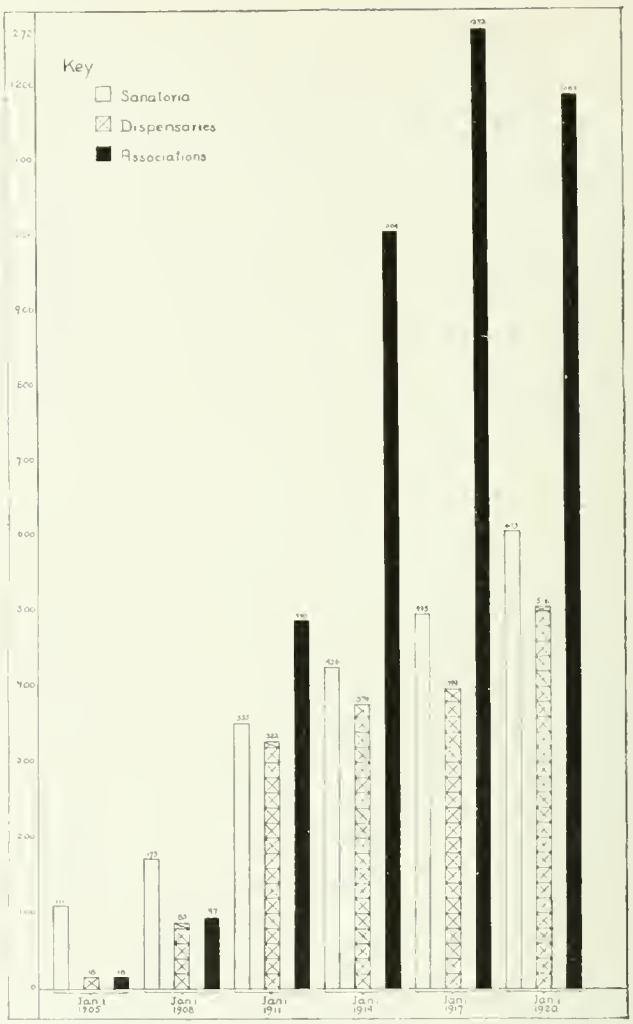
In addition to the work of the various services outlined here, the National Association also conducts the Framingham, Mass., Community Health and Tuberculosis Demonstration. This Demonstration is an effort financed very generously by the Metropolitan Life Insurance Company to see how tuberculosis may be controlled in an average American community.

Definite Policy of Co-ordination

Through its experience of more than fifteen years the Association has developed a number of definite policies. It would be difficult in this space to state all of them. A few of the more general ones, however, might be of interest.

As to associations, most of the state associations have been brought into existence through the efforts of the National Tuberculosis Association and through them in turn the local associations have been organized. In developing relationship with these bodies the National Association has served as a clearing house of information, acted as coordinator, and suggested programs of activity. It has no mandatory powers for the enforcement of programs and policies, but endeavors to offer such sound suggestions that they are readily accepted. By mutual agreement, however, the state associations submit budgets outlining proposed expenditures of funds received from the sale of Christmas seals.

With reference to individuals, the Association has always endeavored to help every person who presented an honest appeal, although it has never been able to dispense relief as such. Its service to the individual applicant has consisted in fur-



A Chart Showing the Growth of the Anti-Tuberculosis Campaign in the United States from January 1, 1905, to January 1, 1920.

The chart is designed to show the growth of the tuberculosis campaign in the United States by the increase in the number of sanatoriums, dispensaries, and associations. The dates given are cumulative in each case, that is January 1, 1911, means all of the sanatoriums, dispensaries and associations in existence on that date. The relative decrease in the number of associations from 1,272 in 1917 to 1,082 in 1920, is not an indication of lack of proper development. It indicates, on the other hand, a more intensified and businesslike reorganization of associations that have previously existed largely on paper, and the substitution in their stead of strong working associations. This meant in a number of states, particularly in New York, a considerable reduction in numbers, but an increase in efficiency.

nishing advice and reference to those who could administer care rather than in giving such care directly. The National Association does not maintain any institutions for the treatment of tuberculosis.

The program of the National Association is entirely one of education, organization and research. In its organization work it has sought to adapt its program to the community. It has always recognized that the problems of one section of the country vary from those of another, and that the solution of the tuberculosis problem in an urban community cannot be applied to a rural one. On the other hand, it has found through experience that well tested methods can be adapted with modifications to almost any part of the United States.

The National Association realizes that tuberculosis is essentially a local problem and that the control of the disease must come ultimately through the perfection of community organization and the development of community consciousness. The national organization may seek to furnish ideas for organization and for standards of work and suggestions regarding methods and programs, but the ultimate development and achievement of the program must be local.

Recognizing that tuberculosis in its various social ramifications reaches almost every avenue of individual and community life, the Association has adopted as a general policy the broadest possible cooperation with health and social agencies, both public and private, that are seeking to relieve human suffering and to promote community betterment. Among such agencies, for example, are the United States Public Health Service and other government departments, the American Red Cross, the American Public Health Association, and the National Organization for Public Health Nursing.

Part of a Larger Health Program

The National Association recognizes that it and its affiliated agencies are only a part of a much greater public health movement. There have been many who have urged either the expansion or merging of the efforts of the National Tuberculosis Association into a broader public health campaign. The Association has wisely maintained its course of specialized effort. So long as approximately one-tenth of all of the deaths of the country are caused by the single disease of tuberculosis and so long as at least one million active cases walk our streets while another million arrested cases are for the most part unaware of their danger, the need for the National Tuberculosis Association is apparent. People generally respond to a concrete appeal, whether one asks for money or for support in a great public effort in which no finances are involved. They are interested in tuberculosis because they know of someone in their own family or their own neighborhood who died of the disease. They are not interested in public health as such, because they never knew of anyone who was sick of public health or who died of public health.

As has been stated above, the National Association and its affiliated agencies have probably made more distinctive contributions to the progress of general public health in this country in the last ten years than any other single agency. On the other hand, I venture to state in closing that the progress both of the tuberculosis movement and of the public health movement as a whole in this country would not have been so rapid had the tuberculosis association listened to the appeal made to it seven or eight years ago to merge its identity with a great general public health effort.

OKLAHOMA HEALTH CONFERENCE

The anti-tuberculosis campaign in Oklahoma has become a general health program. The activities of the very live Anti-Tuberculosis Association in Oklahoma, beginning against the greatest odds, has so coordinated all health activities, and so aroused the general interest and popular support that they have been able successfully to put through most thorough surveys resulting in continuation work in the several communities where the demonstrations were undertaken, in broadening the scope of tuberculosis work to include all the ramifications of organization for a complete health service. The name of the Anti-Tuberculosis Association is henceforth to be the Oklahoma Public Health Association, with Mr. J. F. Owens as president, and Mr. Jules Schevitz as general secretary.

The new régime has had an auspicious initiation in the Health Conference held in Oklahoma City, October 12 and 13, 1920. The scope of the program was made to include rural and urban problems, both from the angle of organization and from civic and individual responsibility. Among the speakers were included the names of such men as Dr. M. P. Ravenel, president of the American Public Health Association, Governor J. B. A. Robertson, Senator R. L. Owen, Dr. S. J. Crumbine, health officer of Kansas; R. H. Wilson, state superintendent of schools; Dr. A. R. Lewis, state health commissioner; and E. K. Gaylord, editor of the *Daily Oklahoman*. The conference was open to the public.

BUREAU OF ECONOMIC RESEARCH

The Bureau of Economic Research, which was organized last February in New York City by private enterprise, opened offices on September 1, 1920, with William T. Foster, M.D.; formerly president of Reed College, as its director. *School and Society* informs us that connections have already been established which provide unrestricted opportunity for the study at first hand of some of the largest industrial enterprises in the United States and Europe. There will be complete freedom for the publication of the results of this research.

THE CRISES OF ADOLESCENCE*

By A. LEVINSON, Chicago

Each individual must find some way to resolve the crises of his own life. Some help may be extended from the outside, but in the last instance self-knowledge and self-control will see him through the external and internal conflicts of life.

The internal struggle becomes acute at adolescence, with danger on the one hand of collapse to the individual whose energy is insufficient, or of ruin from wasted or misdirected superenergy on the other.

The problem of the adolescent is to safeguard his health and his ideals, and at the same time to find means for the sublimation of his highly charged energies.

SOME of the ancient lawgivers set the age of thirteen as the period of the boy's entrance into manhood and twelve as the age of the girl's advent into womanhood. Experience with children has shown, however, that no general rule can be made to apply to the maturation of all children; for not only do children of different races and of different climes vary in their age of maturity, but even children of the same race, living under the same climatic conditions, show individual variations as to the time of maturity. Furthermore, maturity must not be understood to occur in one day. It takes months and even years for the period of ripening to reach its climax. Adolescence comes on gradually during an extended period in which metabolic changes take place in the body whose result is the form of development we call manhood and womanhood.

Marks a Crucial Change

We may regard as extreme the claim of some psychoanalysts that from its very infancy the child's being is governed by the sexual instinct. Aside from the sentimental consideration that such a supposition would rob the babe of what we feel is its greatest asset, innocence, it hardly seems plausible to hold that the child's alimentation and other daily functions are made up of sexual gratifications, even if the word sex be used in its broadest sense. It is safe to assume, however, that adolescence, with all its accompanying phenomena, is not a sudden outbreak but a gradual process which finds its climax at puberty; for adolescence is more than sexuality, it is an acceleration of the metabolism of the body and of the physical and mental processes which manifest themselves in an acceleration of growth, in higher mentality, and in increased energy.

The problems of adolescence are of great importance to the child, the parent, the teacher, the physician and the social worker. False modesty has for many years prevented the free discussion of these problems and we are now paying the price of this reticence. We do not know how to guide our adolescent children and they do not look to us for guidance, but resort to other sources for their information.

Adolescence has been truly termed a crisis, for it marks the crucial change from which some emerge stronger than before while others completely break down under the accelerated metabolism of the body. In proof of this one need only cite such manifestations as the exacerbations of pulmonary tuberculosis at this period from infections that have lain dormant all through childhood, the appearance of toxic goiter, the cropping out of suicidal tendencies, and the complete nervous breakdown that often culminates in dementia praecox.

Just as no two trees, even of the same species, grow exactly alike, so no two children develop in identically the same manner. Many factors influence the character of their development. The course of events in the life of the child depends upon his inherited vigor—which may be termed his constitution—upon his care during infancy, particularly whether he has been breast-fed or artificially fed, upon his susceptibility or immunity to disease, upon his physical and mental training, and upon the numerous factors that enter into his external environment. The many variations these elements may present in different cases only serve to corroborate the fact that all children cannot and do not present the same problems during the adolescent age.

Classify by Energy Potential

Yet in spite of variations in the process of maturity there is one element whose presence or absence characterizes all adolescents, *i. e.*, energy. In the terms of energy all adolescents may be classified in two large, general groups: (1) Those who during adolescence have not enough energy to meet their daily tasks; (2) those who during adolescence possess a superabundance of energy that seeks an outlet. The first group includes

*The seventh of a series of articles dealing with medicosociologic problems in the field of pediatrics prepared for the pages of MODERN MEDICINE by Dr. Levinson.

fewer adolescents than the second, yet many of our children must be placed in this category. There is the child who came into the world prematurely, or the one who was born congenitally weak; there is the child who through the period of childhood has been attacked by one disease after another; and the puny, underfed, undernourished child, the type which becomes a prey to every wind that blows and, unless carefully watched and guided, he may not be able to weather the storms of adolescence.

The greatest need of the child in this group, the child who has not enough reserve energy to meet the new duties thrown upon him is—preparation. The parents must be prepared, and they must in turn prepare the child. A child of this group must not be overworked; he must be taught not to overexert himself, but to conserve the little energy he has. Though a child of this type may make a good showing at school, it is to his eventual advantage if he is not permitted to advance too rapidly. He should be guarded at every step, lest he overstep the limit of his energy tolerance.

The second group represents by far the greater number, including the many children who have during adolescence an excess of energy that seeks expression in numerous ways. The normal adolescent child is a renewed being, with bounding life, new vigor, unaccustomed thoughts. A tingling feeling begins to permeate his being and forge its way forward—the feeling of sex. It perplexes him, bewilders him, and at times threatens to overwhelm him as the crucial point in his development is approached.

At this point the question arises: What can the parent, the teacher, the physician, the nurse, and the social worker do to help the child bridge this crisis safely? Should they offer their assistance? If so, how? My belief is that a great deal of good can be done in this respect, but it must be done early, long before the approach of the crisis. As early as possible the child should be taught the value of self-control, a lesson which cannot be started too early. For greatest effectiveness during adolescence it needs to be begun during infancy and carried out all through childhood. With the moral background of self-control as a bulwark, the parent or teacher can perform a double service for the child during adolescence. He can keep the child of yesterday and the man or woman of today out of mischief, and he can carefully direct the superfluous energy toward fruitful channels—toward study, toward work, toward the building of a happy, healthful future.

Both tasks are difficult and they require deep thought and careful planning for their fulfillment. To keep the child out of mischief, to keep him wholesome in thought and deed, is a difficult task and a delicate one. It is hard to approach the child who may not know anything of the world of grown-ups but who may, on the other hand, know a great deal. Even if one has decided that the child should be taught—and there is now little doubt even in the minds of the most prudish that the child should be taught the truth about himself—the vital question is, what to teach and how.

Beware of Morbid Fear

The child should be taught sexual hygiene, but not in a negative way. He should not continuously be told what *not* to do, nor should he be given lessons in how to abstain from the social evil. Morbid fear and curiosity are aroused by this form of instruction. Far better is it to appeal to the child in a positive way by emphasizing the principle of the conservation of energy, by explaining the law of biological perpetuation in nature, and by showing how it works out in the human world. In a more personal way the child can be told of the value of potential parenthood and of the many ways in which he can influence his life through his actions at the present, adolescent stage. Let him understand that the best that he puts into himself today will come out in him and in his family in later years. Let him be told what it means to a child to be born well, to be happy and healthy. Many of the lessons taught him may lie dormant for a while, but the child stores all these bits of knowledge in his brain and refers to them when the proper time comes.

The direction of the superfluous energy of the child along the right channels is a task that requires a master mind. Unfortunately, but few parents can cope with this situation. Only the parent who is constantly in touch with his child and who has studied his needs and desires since early infancy can find the solution of this problem by directing the child's energy along lines of his natural inclination. Next to the parent, and quite often superseding the parent, is the teacher called upon to direct the child's thoughts and actions. Doubly great is the influence of the teacher upon the child during the plastic period of adolescence. If the modern teacher were not handicapped as she is by having too many pupils and too little remuneration, it would be possible for her to do a great deal more for the child by studying his individual problems and inclinations. If our educational scheme permitted her to devote less time in preparing the adolescent boy and girl for graduation and more time in preparing them for life, how much that would mean to the youth at this most impressionable period of their lives!

Other Agencies Take a Hand

The physician and the social worker can do much to supplement the work of the home and the school. Often neither the parent nor teacher can approach the child. The physician may then be considered the only person who can talk freely to the child on the subject which is at once the most sacred and the most profane. He is supposed to know everything, although many physicians whose advice is deeply sought may not know how to solve their own problems in life. However, as far as his relation to the child is concerned, the physician chosen for this task must be one who has known the child for several years. The family physician who knows the child and the environment in which he has grown up, is, of course, the one best fitted for the undertaking. Next to the family physician in helping bridge the crisis of adolescence comes the pediatrician, whose daily experience with children of all ages makes his advice of value even though he may be a perfect stranger to the child.

The social worker, too, is at times called upon to help the parent settle the difficulties of the adolescent boy or girl. The social worker may be a very important intermediary in cases where the adolescent does not attend school or where the family is not in touch with a physician to whom the child's confidence could be intrusted. In such cases the social worker can do a great deal to bridge the gap between the home and the community, between the child and the outer world of temptations in which he is thrown. By gaining the confidence of the child she can direct him much more smoothly through the many new experiences confronting him and the numerous adjustments he must make in passing from the sheltered world of the home and the school to the large, cold world full of temptations and stumbling blocks.

Clinics for Adolescents

It is to be hoped that the time is not far distant when those who are interested in the welfare of our youth will see to the establishment of clinics for the adolescent, where efficient physicians, nurses, and social workers will be in charge to give advice and instruction to parents on the care and guidance of their adolescent boys and girls. It might at times be best for the parent not to take the child to the adolescent clinic as he would the infant; in fact, it might often be advisable for the child and parent to come separately. This would be an individual problem for the clinic to determine. There can be no doubt, however, of the fact that a welfare clinic for adolescents is a matter of great importance, not only to the individual parent or child who benefits by its instruction and guidance, but to the entire community in which it works. The sooner we are aroused to the need of its existence the quicker may we expect to see its realization.

The Psychopathies of Adolescence

People are waking up to the diseases of adolescence. The field, however, is much larger than the scope of the present day work embraces. The problem now is not only how to handle cases of dementia praecox, but also how to prevent them. The etiologies of all cases of dementia praecox should be studied more thoroughly, but above all it should be realized that the etiology of dementia praecox—a name covering a multitude of sins—should be approached from the standpoint of habit and environment of the child. It would lead one back to the study of nervous children, of meningitis in childhood, of congenital lues, and even to the question of the relation of meningism (conditions simulating meningitis with a negative cerebrospinal fluid) in childhood to diseases of adolescence.

Very interesting would be a study of the relation of convulsions in infancy to disease of adolescence. A study like this would necessarily stretch over a period of many years, but would prove to be very fruitful. Interesting, also, would be the study of the causes of the sudden reappearance of a latent tuberculous infection during adolescence. It is only by a study of the intricacies of adolescence that we may hope to help our children bridge the extremely interesting and at the same time critical period in their lives with the greatest benefit to themselves and to the rest of the world.

CITIES RANKED BY MORTALITY RATES

A graphic chart has been issued by the American Child Hygiene Association which is directed to the thoughtful attention of mayors, health officers, editors, citizens, and taxpayers in the interest of the 2,500,000 babies born in the United States each year. The infant mortality rates for cities are shown by the rank in population. The cities with infant mortality rates under fifty are as follows: Brookline, Mass.; Berkeley, Calif.; Marinette, Wis.; Aberdeen, Wash.; Everett, Mass.; Madison, Wis.; Piqua, O.; and Alameda, Calif.

The quickest and easiest way to reduce a high infant mortality rate, says the bulletin, is to demand the registration of every birth as required by law. It is also the only fair deal for the baby. His citizenship, his right to go to work, and his right to property may depend upon his birth having been registered.

Do you know where your city stands? Your city should ask itself these questions: Are all births registered? Can all mothers get prenatal care? Are our midwives licensed and inspected? Have we child health centers? Is our milk supply pure? Are our school children taught health habits? Do we have medical school inspection?

THE GENERAL PRACTITIONER

NOTHING is more interesting to those of a philosophical frame of mind than to sit still in an easy chair and watch the pendulum of medical thought swing from extreme to extreme until it finally reaches an equilibrium. The gunshot prescription was followed by a period of therapeutic nihilism, and this in turn ended in a burst of glory for Ehrlich's great sterilizing therapy, and today men are still trying to combat by chemical means diseases which were not very long ago considered unreachable.

The days of general practice were followed by the wave of specialism,—a specialism that was without bounds and knew no reason. In one big clinic in this country there was a department for diseases of the organs above the diaphragm and, when a patient with myocardial insufficiency developed an enlarged liver, a colleague from the department downstairs had to be called in consultation. Fortunately, this intense phase of specialism was short lived because of its own limitations. Yet today it is far from dead. Diagnostic clinics composed of a group of individuals, each working on a different part of the patient's anatomy, are becoming more and more common and are replacing the skilled individual practitioner.

It is fair to ask the question: Can such diagnostic clinics ever replace the man who, trained in the school of experience, learns to find, place, and evaluate the symptoms and signs in his patient? Superficially, it would seem that the tremendous ramifications of modern medicine in the fields of correlated science, into industrial hygiene, and sociology would make extreme specialization necessary. But, after all, there is no use in a lot of data brought together by a group of men unless there is some one individual able to sum up information accumulated by the group. Successful practice is never possible unless the patient is considered as a whole with a mind and body, rather than what is in effect regarding him as a bundle of associated organs. Therefore, the head of the diagnostic clinic has to possess certain qualities which, it seems to us, are very closely related if not identical with those developed by the first class general practitioner in the course of his own practice.

Reviewing for a moment the training of the different types of men in medicine, it can easily be seen that the hospital bred man looks at disease as an accomplished fact; by means of careful clinical observation in the wards, controlled by the most exact laboratory methods, he is able to have a perfect grasp of the proved product; but, as Sir James Mackenzie has often said in recent writings, he has not learned to study disease in the incipient stages and he misses the mental training involved in following the course of illness from its very outset. Furthermore, he is at least liable to the great fault of dispensing with his senses and relying upon technical methods of procedure for information which he could obtain unaided. Important and valuable for the scientific study of disease, especially for the advance of rational thought in medicine as opposed to empiric progress, the technical and laboratory developments have lagged behind the clinic in actual practical help to the physician. For instance, the electrocardiagraph cannot be interpreted by anyone who is not specially trained in heart disease and, except in very rare cases, adds nothing to this man's knowledge of his patient's condition. Blood chemistry, which has occupied the field for many years, is in the same position. In the study of diseases of the kidney, for instance, it has not given much of practical benefit which the physician must know to help his patient; in fact, as a recent author commented, the hospital physician is apt to rush into detail at the expense of the whole.

Contrast with this the man who is either unable or unwilling to take the time necessary to pursue the more intensive type of investigation just discussed. Is he any less capable? Is his field any less broad because of this? Of course, the answer depends on the type of the particular individual under discussion rather than the type of work. A man in the country or city who is forced to develop his senses, who must rely on information obtained purely by personal study, must, if he is to develop at all, pretty soon show those traits which Mackenzie believes will guard the future of medical practice. It is he, rather than the hospital physician, who sees disease before the picture is painted in all its colors. It is he who must watch the daub take form, when at first everything seems blurred. Without the facilities for determining non-protein nitrogen, he is able to differentiate kidney lesions; without an expert ophthalmologist, he has to know enough of the ophthalmoscope to interpret an eye ground. Indeed, there are a large number of men doing general work who not only have the burden of individual therapy but must also carry the fight of modern medicine into industry and into the home. It is the general practitioner on whose support any tuberculosis campaign firmly rests. It is the practitioner going into the homes of factory workers who has to realize and correct unhygienic home surroundings.

We believe that the pendulum is swinging to a more wholesome point of view of medicine. Indeed, room is found for every man. There may be supermen in such a scheme, but the general practitioner will form the mass of the army.

THE MEDICAL CARE OF THE NEWBORN INFANT

WHO shall take medical responsibility for the newborn infant? This question recently was discussed before the American Child Hygiene Association held in St. Louis, October 11-13, 1920. Dr. A. N. Creadick of the Yale Medical School made a strong plea for the obstetrician's right to the infant and offered an impressive summary of the satisfactory results achieved under this arrangement in New Haven. In answer, Dr. J. P. Sedgwick of the University of Minnesota not less emphatically asserted that in Minneapolis the obstetric department, which only reluctantly had turned the newborn babies over to the pediatricians, now expresses greatest satisfaction with this change.

This proves a striking divergence of views between the two debaters; but, after all, how unimportant is this dissensus in itself, as long as there is such perfect agreement among them as to the evident fact that the baby is doing very well as long as somebody is interested in it, obstetrician or pediatrician. Both essayists represent well managed university hospitals. Why should they jealously contend for the exclusive right to the newborn infant, if we all so thoroughly agree that in the ideal, modern hospital the patient is not the property of any one physician or any one department, but is justly entitled to the full benefit of the sum total of skill represented in the hospital's medical staff? The child born in the favorable environment of a university hospital is guaranteed perfect safety for these first ten or fourteen days of its existence. It will make not the slightest difference whether in case of doubt the obstetrician consults the pediatrician—or the latter seeks counsel from the obstetrician, who surely possesses better information concerning the mother.

Obviously, however, only a very small fraction of all newborns will be fortunate enough to enjoy such perfect medical care. Our chief concern should be with the many others. It is an incontrovertible fact that the overwhelming majority of infants during the first few weeks of life are not receiving that intelligent supervision, especially in regard to feeding, that is due them. In the home, the physician tends to leave the management of the newborn to the nurse, trained or only practical; or to the mother, as the case may be.

Even in private hospitals the attending physician is inclined to manifest but little interest in the baby, and relies to a large extent on the nurse in charge of the nursery, as a rule a fairly competent woman. This, at least, is the experience of the author of these lines, an obstetrician keenly interested in the normal breastfed baby.

Dr. Sedgwick made the facetious statement that the obstetrical attendant's concern in the main seems to consist in the successful separation of the fetus from the mother, and then is prone to regard the infant merely the by-product of the process. This is a harsh verdict—but who would dare to deny that it contains a great deal of truth?

The present situation is decidedly unsatisfactory and must be changed. Of course, this means that the customary attitude of the physician attending the patient during labor and the puerperium must change. It seems plausible that if he were fully conscious of the great practical importance of this question, and at the same time felt competent to handle the newborn intelligently, he would without fail exhibit the same interest in this as in any other of the medical problems he meets in his daily work.

At present he is lacking in knowledge concerning the specific medical needs of the newborn. Responsibility for this evident deficiency rests entirely with the medical schools. From this viewpoint a discussion between an obstetrical and pediatrical teacher is of some significance. They must settle their dispute concerning their respective competency—not in the interest of those few babies under their care, but for the sake of the medical students, for the ultimate benefit of all babies, born in years to come, under the supervision of these students as future practitioners of medicine.

Instruction in the medical care of the newborn of necessity will have to be given in the maternity wards, as a part of the general instruction in the management of the puerperium. The obstetrician, therefore, offhand would seem the proper man to do it, granted that he is equipped for the task. Otherwise, he will better leave it to the pediatrician. However, under all circumstances the pediatrician must be given free access to the maternity ward. The obstetrician always will be in need of his advice in dealing with suspected or existing anomalies, either congenital or acquired as the result of birth traumatism. It would seem desirable, and entirely feasible, to make previous service as intern in the pediatric department a condition for the appointment to residentship in the obstetric service.

It is of no particular importance who gives this instruction, but it must be given more efficiently than in the past, if we are to secure practitioners both desirous and capable of taking responsibility for the newborn infant. In the hospital the baby immediately after birth might well pass into the hands of a pediatrician; in practice it will ever be necessary that the physician who attends the mother during pregnancy and labor, will attend to mother and baby during the puerperium. H. E.

SURGICAL TREATMENT OF HYDROCEPHALUS

IN A recent publication Dandy[1] reports results of investigations tending to verify his opinions concerning the mechanical origin of internal hydrocephalus. It has been shown that there is practically no absorption of the fluid formed in the ventricles, not until it has passed out through the foramina of Huschke and Magendie into the finer radicles of the subarachnoid space. Any process which would cause a blocking of the flow of fluid, either at the foramen of Monro, in the aqueduct of Sylvius or at the exit from the fourth ventricle, the above named foramena, will cause the fluid to dam back and result in an internal hydrocephalus. Cicatricial stenosis of the aqueduct of Sylvius is, according to Dandy, the most frequent single lesion in congenital hydrocephalus, accounting for about 50 per cent of all cases. The obstruction is a result of inflammation, either the post-natal infections, such as encephalitis, meningitis, etc., or, in the congenital cases, some prenatal intracranial inflammation, of toxic or it may be of bacterial origin; or the obstruction could result from pressure from tumor.

The older the individual the more resistant to injury is the aqueduct. As the fluid accumulates the ventricles expand. In the infant the size of the head increases, but, nevertheless, the increase in size of the ventricles is always at the expense of a greater or less amount of brain tissue. A simple method to ascertain whether or not the hydrocephalus is due to an obstruction is to inject a strain—indigocarmin—into the ventricle. In the communicative hydrocephalus a spinal puncture thirty minutes later will reveal the stain in the spinal fluid. Ventriculography will often show if the obstruction is in the Sylvian aqueduct or at the foramina of Huschke and Magendie. If the aqueduct is patent, air can be made to enter the fourth ventricle by careful injection and manipulation of the head. In these cases the fourth ventricle is usually large.

The operative procedure attempts to reopen the aqueduct. The cerebellum is exposed through a sub-occipital opening, the vermis is elevated and the roof of the fourth ventricle exposed. The vermis is hemisected and the roof of the ventricle split. A fine catheter is inserted into the aqueduct, gently pushed upward until the obstruction is reached, and then, through the obstruction, into the third ventricle. Fluid will begin to flow as soon as the third ventricle is entered. Larger sounds are now used to dilate the passage and, finally, a small rubber catheter is pressed into the newly made channel and left in place for two or three weeks, thus forming an artificial, patent aqueduct. The anterior part of the tube lies in the third ventricle, the posterior part in the fourth ventricle. The tube is anchored to the dura by means of a silk suture. The wound is closed carefully, leaving the tube as a deeply buried foreign body. The tube is left in place as long as possible in the hope that a lumen of epithelium may form, resulting in a channel which will remain patent.

Dandy claims that no ill results have followed the incision into the vermis. He has operated twice by this method. Both patients recovered from the operation; one died a few weeks later of pneumonia, but the second is living and now, one year after operation, seems well and shows no symptoms of hydrocephalus. Dandy pleads for a careful examination, so that the condition will be recognized early, before there has been much destruction of brain tissue.

Editorially, we know of no operation which has proved a success in congenital hydrocephalus and are, therefore, interested in watching the development of Dandy's method, which seems to be based on most careful study and attempts a cure along physiological lines. R. B. B.

PRESERVING HUMAN SERA FOR TRANSFUSION TESTS

LYON* reports that human sera from groups two and three were preserved for a year with 0.5 per cent phenol, and at the end of this time they were perfectly satisfactory for determining the blood group of an individual for purposes of transfusion. The same sera were kept in a dry pulverized state in the icebox and re-dissolved in distilled water containing 0.5 per cent phenol, and also showed good agglutinating properties, but were much inferior to the phenol-preserved serums.

This study seems carefully done and well controlled. These results, therefore, deserve serious consideration, and should be checked by repetition in other laboratories. If these findings stand the test of practical application, they will be of great practical value.

It has been demonstrated time and again that before doing a transfusion it is absolutely essential to perform transfusion blood tests, so as to select a satisfactory donor and thus prevent the serious results which occur when agglutinable blood is transfused. Only in an extreme emergency is it justifiable to perform a transfusion without previously determining that the donor's blood is compatible with that of the patient. By determining both the group of the patient and the group of the prospective donors a proper donor can be selected. In large hospitals and laboratories where transfusion tests are made frequently, there is always sufficient serum from Groups 2 and 3 with which to determine the group of any other blood. Since these sera deteriorate rather rapidly, it is quite a problem in small hospitals to have the necessary sera in the laboratory, or easily at hand. Fresh serum must, therefore, usually be secured at the time of the test from persons known to belong to Groups 2 and 3. In the shifting personnel of hospitals, this is sometimes difficult. Therefore, if, as Lyon's work indicates, sera can be kept almost indefinitely with 0.5 per cent phenol, it will make it possible for all institutions always to have on hand active serum of Groups 2 and 3, so that transfusion tests can be done at a moment's notice. W. T.

THE TYPHOID CARRIER PROBLEM

OSBORN and Beckler,[1] after careful investigation, have come to the conclusion that the axiom "once a carrier, always a carrier," is a good one for health officials to stand by in reference to typhoid carriers.

They have determined that "51 typhoid carriers were apparently responsible for 493 cases of typhoid fever. Of these carriers, 41 per cent transmitted the infection to others by milk; 35 per cent were food handlers, infecting others probably by food. The remaining 24 per cent of the carriers were in such occupations that could have

1. Osborn, Stanley H., and Beckler, Edith A.: Once a Typhoid Carrier, Always a Typhoid Carrier, Jour. Infect. Dis., 1920, xxvii, No. 22, August.

2. Henes, E. J.: Reported at the Tri-State Medical Association, Waterloo, Iowa, October 6, 1920.

caused the cases associated with them by food or by contact."

They determined that the carrier state is intermittent in nature. Some carriers caused no known cases for a period of years, and yet, later cases could be attributed to the carrier, and at this time typhoid bacilli were isolated in his excreta.

Typhoid bacilli were demonstrated in the excreta of a number of individuals many years after they had suffered from typhoid fever. The attack of typhoid fever had occurred from sixteen to forty-four years prior to the first case traced to different carriers.

Some carriers whose gall bladder harbored typhoid bacilli remained carriers even after the gall bladder was removed.

Too much emphasis cannot be placed on the importance of securing three release cultures from the stools and urine of recovered typhoid cases before they are allowed again to enter upon their usual daily life.

Osborn and Beckler have used the usual laboratory methods of isolating typhoid bacilli from stools and urine. These methods are perfectly satisfactory, but attention should be called to a more recent method which might determine a carrier state when this cannot be determined from bacteriological examination of stool and urine. Henes[2] has reported very interesting studies of cultures of duodenal contents secured by means of a duodenal tube in convalescent cases of typhoid fever. In some of these cases typhoid bacilli have been isolated from the duodenal contents when they could not be isolated from the stool. This is a comparatively simple procedure, and should be added to the already established routine examination of recovered cases of typhoid fever before these cases are released from the hospital or from home.

The almost complete control of typhoid fever, from the epidemiological point of view, which has been accomplished in recent years should not allow the medical profession to become complacent over the contagion of typhoid fever, but should spur the profession to be both on the lookout for typhoid carriers and to make universal use of typhoid vaccination. W. T.

THE TOXIN, STREPTOLEUKOCIDIN

NAKAYAMA[1] has demonstrated that in cultures of Streptococci, especially when this organism is grown in a mixture of broth and either goat serum or horse serum, that a soluble toxin develops which destroys leukocytes. This toxin, which he calls streptoleukocidin, appears to be distinct from streptolysin. A characteristic of streptoleukocidin is that it destroys leukocytes; a characteristic of streptolysin is that it dissolves red cells. Streptoleukocidin prevents the phagocytosis of Streptococci by leukocytes.

Antistreptoleukocidin was produced in the serum of rabbits by injecting streptoleukocidin at intervals of three to four days. This antiserum was able to neutralize the toxic leukocidin when tested *in vitro* by the usual opsonic methods. The leukocidin completely prevented phagocytosis of Streptococci, but, when antileukocidin was also present, the leukocytes were able to take up an average of eight Streptococci.

No report is made of the clinical use of the antistreptoleukocidin sera. Since the antistreptococcus sera which are available have been demonstrated to be valueless in the therapy of severe Streptococcus infections, it is hoped that this antistreptoleukocidin serum will be tested out clinically. If this antiserum becomes generally available, it is of importance to test its efficiency in clinical cases. W. T.

HYPERCHOLESTERINEMIA

BURNS[1] has demonstrated in a case of a rare disease, xanthoma multiplex, that the deposit of cholesterol in the skin is the cause of these skin lesions, and also that the condition is marked by a great excess of cholesterol in the blood. The presence of cholesterol in the skin lesions verifies previous work of Pollitzer and Wile.[2]

This investigation is of especial interest to the dermatologist, but should be of interest to physicians in general, in that it calls attention to the importance of cholesterol blood determination. In a recent issue of this publication, attention has been drawn to the relationship of hypercholesterinemia to pregnancy and to cholelithiasis. This careful investigation of Burns is mentioned here to emphasize the importance of adding blood cholesterol determination to our routine in the clinical laboratory. W. T.

SPREAD OF SPIROCHAETA PALLIDA

BROWN and Pearce* have reported a review of some extremely important investigation which they have made on the rapid dissemination of Spirochaeta pallida from the primary focus of infection.

This problem was studied by producing a syphilitic lesion in the scrotum of rabbits and determining how soon after inoculation a primary lesion appeared on the scrotum and how soon Spirochaeta pallida could be demonstrated in the inguinal lymph nodes and in the blood stream. It was found that the inguinal lymph nodes contained Spirochaeta pallida less than forty-eight hours after the time of inoculation. It was also found that as early as one week after inoculation, Spirochaetae were present in the blood stream. This was determined by the ability of the inguinal lymph nodes and the blood to cause syphilitic infections in other rabbits.

As the primary lesion in the skin of the scrotum did not appear until about a week after inoculation, it can be seen that a wide dissemination of the Spirochaeta was present in the rabbits even before the primary lesion appeared in the skin.

The authors state that these results cannot be transposed directly to the consideration of the dissemination of the infectious agent in human cases of syphilis. Nevertheless, these data are very suggestive of a similar dissemination of the Spirochaeta pallida in syphilitic infections in man.

The results of these experiments should be considered to be of extreme importance to clinicians. They show that at no time can a syphilitic infection be considered a local disease, and therefore that every syphilitic infection should be considered and treated as a syphilitic infection of the entire body. This means that as soon as the diagnosis has been proved, even though only an insignificant primary lesion is present, vigorous antisyphilitic treatment should be at once instituted and continued.

The second important lesion to be learned is that local excision of a primary syphilitic lesion is incapable of

*Brown, Wade H., M.D., and Pearce, Louise, M.D.: A Note on the Dissemination of Spirochaeta Pallida from the Primary Focus of Infection, Arch. Dermat. and Syph., 1920, ii, No. 4.

ridding the patient of the syphilitic infection. By the time the initial lesion is manifest, the infecting microorganism has spread widely throughout the body. It would be a false security to believe that simple excision of the primary focus removes the syphilitic infection from the patient. The procedure of excising a primary syphilitic lesion has fortunately been practised only infrequently, and now has no justification whatsoever.

This excellent investigation completes another chapter in the study of syphilis, and demonstrates that one must observe extreme vigilance and thoroughness in treating cases of syphilis. W. T.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION

The program presented by the Mississippi Valley Medical Association at its forty-fifth annual meeting in Chicago October 26 to 28 exemplifies the marked degree of excellence which may be brought out in a program of this kind. Specialists of unquestioned achievement presented the several subjects and related materials and contributory studies were so grouped as to coordinate the best work that is being done in the several fields.

The address of the president, Dr. Frank B. Wynn[1], of Indianapolis, Ind., dealt particularly with the development of specialties in medicine and the decline of the general practitioner. He declared that this has resulted in a spirit of materialism, although specialism must be credited with material contributions to the science of medicine. The material success that has attended certain specialties has had an indirect result in a loss of prestige on the part of the specialist on account of his desire for money, but the strictly ethical specialist has realized the shortcomings of the over-development of the specialties and has made a sincere effort to get away from them. The penchant for specialism has undoubtedly led to a broadening of elective subjects in medical education. In a particular instance reported, the postgraduate student in medicine stated that he was taking "some surgery and some pathology." The tendency just now emphasizes the importance of general information. This is especially of value in the matter of making a diagnosis, as it is most essential that the patient be considered as an individual, taking into account his psychology, home environment, and his business. The highly specialized man, with his eye on the pathologic gall bladder, can operate for and relieve the local condition, but it does not necessarily follow that his work is worth while. Among a great many surgeons there is a tendency to operate to find out what is the matter; but, according to Dr. Wynn, real skill consists in making the diagnosis to determine the disorder, and in most cases the operation should merely verify a diagnosis previously worked out.

Dr. Louis B. Wilson, of Rochester, Minn., presented a careful statement of the present status of pathology as related to other specialties. Incidentally he analyzed the report of the Council of Medical Education to the American Medical Association as it relates to the status of the pathologist, his underpay, and faulty qualifications as a member of the clinical staff. Dr. Wilson considers that pathologists fall into two groups, (1) the pre-clinical group, who, for teaching or technical purposes, are chiefly concerned with the experimental laboratory; and (2) the clinical group. A pathologist qualified to fall into the latter category, according to English tenets, should, up to the age of thirty-five, not be specialized to such a degree that he would be unable at any time to carry on clinical work successfully. Dr. Wilson would extend to the age of sixty-five the period in which the pathologist should be so close to the clinical aspects of the material he handles as to be perfectly competent to handle the clinical as well as the pathologic end of the cases. He placed great emphasis upon the importance of professional acquaintanceship as contributing toward personal standing and respect, as well as toward correlation of knowledge and readiness in its command. In order to provide a qualified man for the head of a pathological department, such a post should, in his opinion, command $10,000 a year, with $7,000 for his assistant, $3,000 or $4,000 for instructors, and from $1,000 to $2,000 for fellows. The total department on a right basis would cost about $40,000 a year, which sum he proposed to secure from beneficent individuals. As to the shortage of pathologists, Dr. Wilson said that at the close of the war the card catalogue of the Surgeon General's office showed 750 pathologists, and he had a personal knowledge in addition to that of most of the leading men in the country. Of repeated calls he has had to recommend men for appointment in pathology, which would in the aggregate run perhaps to 750, he has been able to supply only two. Inquiry made throughout the country among pathologists has developed the fact that even if they could afford to pay a high stipend, the men cannot be secured, and in the Mayo Clinic they find the pathologic service the hardest of any to fill.

The address in surgery by Dr. Charles Mayo, of Rochester, Minn., dealt with the surgical treatment of peptic ulcer. He gave details of the management of this operation and its success in the series of the Mayo Clinic. He advocates resection for the cure of peptic ulcer because a condition of this kind affords a chronic irritation which favors the genesis of cancer. Cancer has in a given per centage of cases developed upon the site of an old ulcer, the cultures in these cases having been obtained from the walls of the ulcer, not from the ulcer itself. He attached some importance to the possibility of recurrence, as jejunal ulcer, after resection, which may result from a stoma left too large or too small, too long a jejunal loop, or the improper application of the jejunum to the stomach.

The symposium on the disorders of the internal secretions was comprehensive and ably treated. Dr. Walter B. Cannon gave a rapid summary of his work on the thymus and adrenals. Others taking part in this symposium were Dr. John L. Tierney, St. Louis, Mo.; Dr. S. E. Bandler, New York; Dr. George H. Hoxie, Kansas City, Mo.; and Dr. George Draper, New York.

The symposium on the problem of the primary anemias was led by Dr. Charles P. Emerson, of Indianapolis, who discussed it from the angle of the internist. Dr. Emerson thinks it is to be deplored that the disease has received an appellation that is drawn from the end picture of the condition, that, when a diagnosis can be definitely made from the microscopic picture of the blood, the patient is beyond help other than palliative measures. In dealing with these cases one must always bear in mind that spontaneous remissions tend to occur and undue optimism is to be guarded against. He has seen remarkable benefit to the patient from heliotherapy. The surgical aspects of the condition, according to Dr. Willis D. Gatch, have problematic value, the analyzed results of published data being, on the whole, unfavorable. Virgil H. Moon discussed the pathologic considerations.

The surgical and pathological considerations of tumors of the bladder were handled, respectively, by Dr. Hugh Cabot and Dr. A. S. Warthin, both of Ann Arbor, Mich.

[1] The presidential address, "Present Trends in Medical Practice," by Dr. Frank B. Wynn, will be published in the December issue of MODERN MEDICINE.

NERVOUS AND MENTAL DISABILITIES AS RELATED TO EFFICIENCY

By LEWIS J. POLLOCK, M.D., Chicago, Ill.

ONE of the lessons taught by the late war concerned itself with the importance of nervous and mental disabilities as related to the efficiency of a cross section of our young population. The necessity for this study and treatment of mental deficiency was glaringly demonstrated. The social gain obtained by placing individuals of particular intellectual levels to tasks corresponding to their capabilities, was emphasized. The prophylactic value of weeding out neuropathic material was proved by the relatively low incidence of war neuroses in our army.

Concrete Evidences of Gain

That which we have learned at such a cost must now be applied to our problems of social and industrial medicine. It is gratifying to point to some concrete examples of the recognition of the importance of the problems of mental deficiency and the hygiene of childhood.

In 1913 the state of Ohio authorized the creation of a Bureau of Juvenile Research. In 1915 there was appropriated $100,000 for the erection of buildings where these children may be cared for while under observation. These buildings are now under construction. The law particularly emphasized that this was to be a research institution. Henry H. Goddard, its director, states that "part of its function is to study these cases with a view of discovering some solution for the many problems of juvenile delinquency and abnormality."

The State Commission for Mental Defectives of the state of New York has submitted to the legislature of that state its first general report.[1] The general policies of this Commission are expressed as follows: "A state program for the care, training, segregation, and supervision of mental defectives may be conceived as being (1) institutional; (2) extra-institutional.

Institutional Requirements

"Institutional facilities must be adequate or else the program will fail in most particulars. These facilities will vary somewhat in type, according to the section of the country, the particular interests of superintendents, and boards of managers, and whether the institutions are intended to provide training, permanent segregation of low grade inmates, or long continued segregation of defective delinquents. There should be detention and observation hospitals where certain cases of suspected mental defect may be sent for careful examination and classification.

Extra-Institutional Facilities

"Extra-institutional activities for a state wide program for mental defectives include: (1) the mental examination of backward school children; (2) special classes in the schools; (3) mental clinics, both fixed and movable; (4) after-care of special class pupils; (5) supervision of cases and paroled and discharged from the institution; (6) special training of teachers; (7) census and registration; (8) identification and supervision of all uncared for defectives and the selection of those who need institutional care; and (9) stimulation of scientific research. In some of these matters the work of the Commission should be merely in the line of cooperation with other state departments, notably the state department of education. In the matter of school children, it should begin its activities when the department of education leaves off; for example, examination of the backward school children is essentially a function of the Department of Education, but the Commission for Mental Defectives should be kept informed of the results of these examinations, and should assist in proper provision, when this is necessary, for these cases after the school period. Mental clinics will be referred to in more detail in a subsequent paragraph. They should be operated, for the present at least, in conjunction with other state departments, notably the State Hospital Commission and the State Department of Health. A census and registration of the feebleminded should be made by the Commission, although this will be a matter of gradual progress and possible only when the whole program is working smoothly. The Commission should have attached to it social workers to provide for the extra-institutional supervision of all uncared for defectives in the community.

"The necessity for such a commission is seen when we review the statement that 'Conservative estimates from various sources agree in showing that there are at least 40,000 mental defectives in New York state outside of institutions, while the state is caring for only about four thousand, or one-tenth. Forty thousand beds for mental defectives will probably never be required, but the discrepancy between these figures is too great to be overlooked, for undoubtedly more than one defective in ten requires institutional care.'"

What Care Accomplishes

A concrete example of what may be accomplished by the psychologic study of atypical children and their proper teaching is offered in the pages of the *Psychological Clinic*.[2] Included in the issue referred to are details of cases described, among other, by Lightner Witner, Sarah Warfield Parker, and Gladys E. Poole.

Widespread attention should be directed to such studies, not only among physicians, psychologists, and teachers, but the general public. The indifferent neglect with which such cases are so frequently treated, often for selfish reasons, contributes in no small degree to the impoverishment of the state and society.

The necessity for "cooperation between the psychologists and psychiatrists"—which should include the general practitioner and neurologist—is emphasized in a communication by Morris S. Vitteles, M.A., who deals with "A Case of Loss of Psycho-motor Control, Suspected of Malingering."

The patient was discharged from a hospital of the United States Army with a diagnosis of malingering. At the Psychological Clinic of the University of Pennsylvania he was said to present the symptom-complex of "profound hysteria."

From the standpoint of nomenclature it would be preferable to classify such a case as one of hysteria showing a loss of psycho-motor control. The necessity for the

2. The Psychological Clinic, May 15, 1920, xiii, Nos. 4-7.

cooperation for which Vitteles pleads is well demonstrated by his own exposition of certain elements of his article. He states that "The conditions which motivated the physician in the Army hospital to discharge the subject as a malingerer are unknown to us." It seems clear to the reviewer that the conditions had to deal with diagnostic ignorance, if the patient really suffered from hysteria. One of the objects of the author's examination of the subject was "to determine whether such symptoms as the gait, the fatigue, the intentional tremor, the stammer, etc., were consciously and intentionally falsified—whether, in other words, there was an actual functional defect in psycho-motor control."

Having once demonstrated the loss of psycho-motor control, he is satisfied, but makes no attempt to satisfy us, that no case showing defect in psycho-motor control can present this deficiency as part of a conscious and volitional hypothecation. Inasmuch as the only practical clinical difference between a case of malingering and hysteria is the consciousness or unconsciousness of the hypothecated symptom, if, the demonstration of the presence of a deficiency of psycho-motor control spoke for the unconsciousness of the process, we would have a royal road to the differential diagnosis between these two conditions. It seems to the reviewer, however, that the psychologist may well be fitted to determine the degree of psycho-motor control but that only a trained and experienced neuropsychiatrist can determine whether the gait, intential tremor, and, among other symptoms, the loss of psycho-motor control, is functional or organic; and, if functional, whether hysterical or malingered.

NEO-NATAL MORTALITY

The Frederick A. Packard lecture of the Philadelphia Pediatric Society was delivered this year by Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P., Lond., and is reported under the above caption in the London *Lancet*, May 22, 1920. The foremost position in medico-sociological history in the last fifty years must be given to the steady decline of the birth rate which has occurred in most civilized countries and to the increased emphasis placed upon the welfare of infants and their mothers, he says.

The first part of his lecture is devoted to a minute analysis of the causes of deaths in infants, and especially to deaths which occur in the first month after birth. The medical certification of deaths among infants is much less satisfactory than for deaths of any subsequent age, and he considers it futile to advise physicians to be more accurate in their certificates until we have more pathologic knowledge of early infant mortality. He urges that this early infant mortality is in large measure preventable. Among the causes of these deaths he assigns, in their order of prominence, the following: (1) enormous differences existing at the time of birth; (2) the varying prevalence of syphilis in different circles, the rate from syphilis in illegitimate children being eight times as great as that for legitimate infants; (3) inadequacy of the care of the health of mothers in the interest of preventing stillbirths; (4) the lack of care for unmarried mothers and for their infants; and (5) the variations in the incidence of sickness and deaths of mothers during pregnancy and child bearing.

In his survey of possibilities of improvement, Sir Arthur makes a number of practical suggestions as to what it is desirable for public health authorities to do generally in order to enable every mother and infant to have the best care which modern medicine renders available. The first and most essential feature he takes to be continuity of supervision, this to be provided through ante- and post-natal clinics and skillful care during parturition, a raised standard of midwifery practice, and further research in ante-natal pathology. No social work is so certain to give immediate results in the saving of maternal and child life, in reducing invalidism of mothers, and in enhancing the national welfare as the immediate provision in every area throughout the country of maternity homes and hospitals for a considerable proportion of normal confinements and for the majority of complicated cases.

STANDARD ANESTHESIA RECORD

As a part of their program seeking better methods, and promoting better practice by anesthetists throughout the country, the National Research Society has designed a chart which is considered to embrace all essential points in the administration of an anesthetic and to leave such a record as will speedily show the surgeon, anesthetist, and nurse the history of their case. This chart has been designed to show what happens to the patient and how he reacts to the various factors that bear upon his case. Detailed records of this nature have been all too few, and

the requirement of such records will stimulate better work on the part of all.

The chart was devised after studying and comparing charts from all leading hospitals and clinics of the United States by a committee consisting of Drs. A. H. Miller, Providence; E. I. McKesson, Toledo; and A. F. Erdmann, Brooklyn.

BRITISH MACE TO AMERICAN COLLEGE OF SURGEONS

THE opening of the Clinical Congress of the American College of Surgeons, which took place on the evening of October 11 in Montreal, was made the occasion for the formal presentation to the American surgeons of a silver mace as a demonstration of international amity, and of the formal appreciation of the services of American surgeons during the world war. The presentation was made by Sir Berkeley Moynihan, C.B., M.S., F.R.C.S., of Leeds, England, supported by two colleagues, Sir William Taylor, C.B., of Dublin, Ireland and Mr. Albert Carless, C.B.E., F.R.C.S., of London, England. The mace is inscribed: "From the Consulting Surgeons of the British Armies, to the American College of Surgeons, in memory of mutual work and good fellowship in the Great War, 1914-1918."

The symbolic message was worked out most successfully by Omar Ramsden, whose handicraft is widely known. Hand wrought, in silver gilt, with chiseled and repoussé work, the mace is designed along traditional lines and proportions of the civic British mace of the Seventeenth Century. The rod upon which the mace is built is of British oak, taken from a tree more than a thousand years old, at Wytham, in Berkshire. The stand upon which it rests is oak from the same tree. The main body or head of the mace is separated in six panels by the Winged Caduceus, an ornamental version of the badge of the United States Army Medical Corps, and each of these panels is choicely engraved in delicate and detailed repoussé work presenting the full Blazon of the United States of America, the Dominion of Canada, the Royal College of Surgeons of England, the badge of the Royal Army Medical Corps, the shields of arms of John Hunter and Lord Lister, Britain's two greatest surgeons, and a cartouche bearing the words "Philip Syng Physich, 1768-1837, Father of American Surgery."

On the lower portion of the head is to be found a band symbolically representing water and indicating the broad ocean that both separates and unites the United States and the Mother Country, the latter being symbolized by brackets in the form of British lions, beautifully chiseled, and supporting the head and terminating the upper portion of the staff, the claws of their feet gripping a hammered decoration which is designed to represent American and Canadian maple seed pods and heart shaped spaces, all protected by solid, jewel like bosses of exquisite chiseled work.

The staff itself is also symbolically engraved with a fine design embracing the national floral emblems of the United Kingdom—rose, thistle, shamrock and leek, and entwined among these are numerous ribbon scrolls upon which are engraved the names of the donors of the mace.

Three feet eleven and one-eighth inches long, and weighing 140 ounces Troy, this beautiful example of antiquarian and heraldic work embodies in the designs briefly recounted above a message of good will, good fellowship and spiritual ties that bind together British and American hearts. As Sir Berkeley Moynihan himself puts it: "We do want to visualize in permanent and enduring form the ties, both physical and spiritual, that link the English-speaking peoples of the world. We are one spiritually, and in this mace we have tried to give expression to that faith and that belief.

"On the fields of Flanders and France, Humanity recovered its rights. In the grave and anxious days of war no friendships were deeper or more intimate, no joint labors more fruitful than those which took place between the members of the profession of America and of every part of the British Empire. We then gained each for the other not respect and sympathy alone, but true affection also. Every lover of his own country and every lover of humanity must wish that the spiritual alliance thus created shall endure to the end of time. In our desire to perpetuate the memory of those days of duty done together, we, the representatives of the Consultant Surgeons attached to the British Army during the war, ask you, the American College of Surgeons, here in session in one of our great Dominions, to accept this mace as a symbol of our union in hard days of trial, as a pledge of our devotion to the same imperishable ideas, and as a witness to our unfaltering and unchanging hope that between the professions of these countries there may exist a brotherhood forever in the service of mankind."

The President, Dr. Armstrong, responding, said:

"I accept this beautiful mace, presented by you on behalf of the Consultant Surgeons of England, with thanks and with full appreciation of the care and thought bestowed upon its design and construction. We accept it as a token of the cordial relationship that obtained between the surgeons of the two great nations here represented. It is a symbol of the zeal and enthusiasm, in our art, which, arising in the Old World, has spread to the New World, and we shall endeavor on this western hemisphere to keep the sacred flame of science burning not less brightly as did our forebears in Great Britain. It will remain with us as an emblem of unity, a work of art, a remembrance of the great effort of the two great English-speaking nations to give truth, liberty and justice to all peoples and to all nations. The scientific fire presented in this gift welds another link in the chain that binds us forever in united effort to promote the highest possible standard of surgery, as well as peace and good will among men."

At the conclusion of the session the members of the American College of Surgeons were given a brief insight into the stately methods of the older institutions of learning, when the mace bearer, in the khaki of a British medical officer, shouldered the newly presented brazen emblem of authority, and the gowned and hooded authorities of the college, preceded by the mace, left the auditorium in processional form, with the dignitaries on the platform.

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

PSYCHOLOGY OF INDUSTRIAL LIFE

OF COURSE, psychology enters largely into industrial life, and in order to have a healthy and contented body of workers they must be studied from the psychological aspect and as far as possible their need and idiosyncrasies complied with. These facts are beginning to be recognized in this country and, as evidence of this growing comprehension on the part of scientific, medical, and practical men, the Section of Psychology at the meeting of the British Association held in Cardiff, Wales, during the week commencing August 23 last was perhaps the most popular of all the sections. Several papers of peculiar interest were read. Among these was one by Mr. F. Watts who, dealing with problems of vocational selection, said that an indispensable preliminary to the correct psychography of vocations, without which vocational selection could take place only in an unscientific fashion, was the determination of the relations between general ability and the specific aptitudes called for in the performance of particular tasks. Until the psychography of various industrial occupations had been successfully accomplished, it would be advisable to construct vocational tests in such a way as to produce the mental conditions of the work for which it was attempted to diagnose fitness. So far, the vocational psychologist had attempted to proceed on the assumption that intellectual qualifications alone decided vocational fitness, but an analysis was desirable which would take other factors into account.

Mr. S. Wyatt read an extremely illuminative paper on "The Psychology of Industrial Life," in which he narrated the results of observations made during an investigation of the cotton industry under the auspices of the Industrial Fatigue Research Board. He pointed out that, as a rule, it was found that the operative was highly suspicious of any change in the industrial environment, especially when the cause of the change was the employer. Speaking of the different processes carried on in the industry, Mr. Wyatt said that though it was probable that a certain amount of monotony exists in weaving, in no other occupation of any importance had the female worker the satisfaction of so completely transforming the raw material into the finished product. The numerous stoppages of the looms, together with the noise in the weaving shed, kept the weaver at her loom and made sustained conversation impossible. The least distraction was welcome. Unconscious efforts to relieve monotony seemed to be expressed in the amount of hair-dressing which took place in the sheds. An interesting feature of life in the weaving shed was the sympathy and cooperation which existed between the operatives. Whenever a weaver had an unusual number of breakages in the cloth she was producing, the operatives in her immediate vicinity immediately came to her assistance. The more skilled workers were always willing to help the less skilled. The speaker said that discontent was much more noticeable among men workers than among women workers. Another speaker made the apt remark that the monotony of a process must be considered in relation to the capacity of the worker. A worker might be content with a monotonous process from lack of initiative.

Professor E. L. Collis, who, by the way, has just published a very able work dealing with various phases of industry from the medical, hygienic, and psychological standpoints, read the chief paper of the Section, the paper being entitled the "Psychology of Industrial Convalescence." He said in part, that the nation had recognized the need for dealing with convalescing disabled soldiers. The most successful treatment had been found to be that with an occupational objective, the reason being that occupational therapy was practical and largely psychological. What was only just coming within the realms of national conscious thought was that for many years industry had been providing and would continue to provide as many disabled persons as did the war. Experience with disabled soldiers had demonstrated how few disabilities were sufficiently serious to cast a worker upon the industrial dust heap. The strain of industrial life in peace time was just as productive of neurasthenia—machine shock if they choose so to call it—as the conditions of active military service. Industry could be made a unique therapeutic agent; what was required was a hair from the dog that did the biting. Industrial neurasthenia played an important part in every illness which befell a worker, whether due to accident or disease. Such a worker required confidence in the future to enable him to resist the onset of illness or to enable him to recover. This confidence could be created only by the master he served, industry. The size and complexity of industrial concerns made the duty of creating this confidence a matter to be delegated by the firm to a special branch of management containing within its personnel medical and social experts.

Referring to particular types of cases, he suggested that a worker who was recovering from injury should have his convalescence facilitated by readmission to work for part time under medical supervision. Then there was to be considered the case of the loss of a limb. Men crippled in the war were fitted with artificial limbs, taught to use them, and encouraged to learn a new occupation. He submitted that a moral obligation rested with industry to finance treatment on these lines. Industry ought to provide means for industrial convalescence. What might be hoped for was that the dominant industry of each district would be developed at each place, rather

than an effort to develop indiscriminately. Then, convalescing skilled workers from one district could, if necessary, be transferred to their own special trade carried on in another. In the Physiological Section of the same meeting Dr. F. S. Lee, professor of physiology in Columbia University and consulting physiologist to the United States Public Health Service, dealt with "Some Phenomena of Industrial Fatigue." He pointed out that the hourly output in physiological operations was practically always increased by a diminution of hours, but the effect on the total output depended on the balance between increased productive power and lessened hours of work.

In the very severe tasks of the millmen in the tinplate manufacture Vernon found the total output to be 8.3 per cent greater in the six hour than in eight hour shift. But this lent no support to the argument for a universal six hours day. What period, indeed, represented the most nearly universal optimum for a working day was still an open question. A comparison of the diurnal curves of the output of the eight and ten hour factories investigated by the Public Health Service showed that a conspicuous feature of work on the eight hour plan was its steady maintenance of output in contrast to the fluctuations of output of the ten hour plan. Each added contribution of observation and experiment appeared more and more to support the view that from the standpoint of physiological essentials the optimum working period was comparatively short, but varied in duration with the kind of work performed. Eight hours was probably too long for certain kinds of work and too short for others. A universal eight hour day would be unscientific. Recess periods during the working spell nearly always resulted in increased hourly output and frequently in increased output for the whole day.

LONDON CORRESPONDENT.

PREVENTABLE LOSSES IN CASUALTY INSURANCE

BY JOHN C. A. GERSTER, M.D., NEW YORK CITY

DURING the past two years experience as surgeon to a hospital for the re-education of industrially crippled, and as surgical advisor to a casualty insurance company, the author has been repeatedly impressed with the amount of unnecessary and readily preventable disability encountered in the course of his daily work. In the field of fractures alone enormous aggregates have been paid out for disabilities which might have been easily prevented under different management on the part of the companies themselves.

Expert Buying of Surgery

In striking contrast to the policy of life insurance companies which make it a point to keep abreast with scientific medical progress affecting their interests, the casualty insurance companies as a body have gone on their way unheeding the common basic principles of accepted surgical practice as applied to their own field. With minor exceptions here and there, the great surgical advances made in the last war have gone unheeded, with the result that, through a faulty system of claim management, fingers, hands, arms, and legs have been permanently disabled, and have had to be compensated for by insurance companies. Why? Because of their failure to appoint *expert buyers* for the commodity, surgical treatment. However capable he may be, certainly no claim agent can have expert surgical experience; and yet his superiors have deputed to him the purchase of surgical services. He is saddled with an unfair responsibility and must muddle through the best way he can. How does this work out? On the one hand, just bills for good work are often questioned; while on the other, in the payment of surgical bills sometimes representing poor work, carefully itemized bills are passed because of their appeal to the non-professional mind. In paying for surgical work not a thought is given as to whether the amount paid corresponds to the time consumed and skill displayed:—yet upon these two factors depends the whole problem. In a recent series of 220 healed simple fractures of the extremities with marked disability, referred to an industrial rehabilitation hospital for possible improvement, the vast majority of the cases showed readily preventable deformities. In other words, these deformities represented a vast sum paid out for preventable disability. Until casualty insurance companies make it their business to see that their injured receive up-to-date surgical treatment within two or three hours after injury, they will continue to pay about twice as much as they should for disability following injury.

The surgical experiences of the great war have shown the following basic truths:

(1) That infection can be controlled and often absolutely prevented if contaminated wounds receive proper surgical treatment within eight hours after injury.

(2) That, if a surgeon fails to obtain good results with the Carrel-Dakin treatment, the fault is with himself, not with the method. There *are* surgeons who *do* obtain good results with this method.

(3) That fractures are emergency conditions requiring prompt reduction at the earliest possible moment after they have been received. It is better practice to reduce a fracture as well as one can without the use of the x-ray than to let it alone and wait until an x-ray has been taken if such delay entails the loss of several hours.

(4) That in many cases the suspension and traction method for fractures of the extremities gives in minimum time a good function with no shortening. At one hospital with a large fracture service patients with fractured femurs begin walking at the end of thirteen weeks under this method. Naturally, it takes somewhat longer than this before they can walk without a limp.

(5) That divided tendons and nerves must be immediately repaired.

What Results to Demand

These are only a few of the self-evident surgical principles upon which claims departments should base their system of administration. Have any claims departments done this? Are there any which make provision for routine telephonic reports as soon as accidents have occurred? Are there any that provide surgical consultants to aid those surgeons doing casualty insurance work who have not had the benefit of experience in war surgery? Are there any claims departments that realize that a result that shows little or no shortening in simple fractures of the long bones, plus at least 75 per cent of normal joint motion can be demanded from the surgeon provided he receives the case in time? Are there any

that classify their results, and from a study of this classification seek to improve methods employed in administration or treatment? Is there a medical intelligence department that keeps track of the injured man from the time he is hurt until he is well? If there is, the matter has not been reported.

Do the casualty insurance companies realize what they have a right to expect from the hospitals to which they send their injured for treatment? Do they realize they can demand the same efficient service which obtained in certain army casualty clearing stations during times of relative quiet at the front? That x-ray men as well as surgeons should be on emergency call? That the x-ray room should be close to the operating room? That portable x-ray machines should be used for control of fractures treated by suspension and traction? That inexperienced interns should not be permitted to repair divided tendons in poorly equipped accident wards? That if these requisites are not provided, the hospital's trustees can be asked by what right their institutions accept cases for which adequate facilities have not been provided? Should local hospitals not prove amenable to constructive criticism, then it might be considered whether industry itself could not undertake increasing industrial human salvage by the organization, equipment, and management of large hospital centers with related dressing stations throughout the country; the personnel of these centers to include leaders in medicine and surgery.

How can the companies know what sort of surgical service they are paying for unless they employ an expert to advise them? It takes fifteen years to make a surgeon, and yet they expect their claims men—familiar with accidents but not with surgery—to sit in judgment, to pass on the quality of surgical service, to estimate technical ability, to hire and fire as they see fit. There result losses, the extent of which is not even suspected.

Let us review a glaring example of unnecessary loss which occurred a short time ago. A man with a simple fracture of the shaft of the femur, improperly treated, at the end of four months showed a shortening of two and three-fourths inches, angulation at the site of the fracture, a stiff knee, and a stiff hip. In addition to the condition of his lower limb he would be likely to develop spinal curvature unless he wore a high soled shoe for the rest of his life. Any claims man knows what compensation such a limb carries; yet what claims department would not look with horror upon a bill of three hundred to five hundred dollars for surgical treatment of this condition which would prevent shortening and result in good joint function? One can hear the exclamation: "But we cannot afford to pay such high prices!" Yet in that department no more than a casual regret would be expressed at paying $5,000 and upwards for the disabling deformity just described, which could have been prevented. In other words, according to present methods, they cannot spent $1,000 for surgeons and hospital expenses to effect a saving of at least $4,000 in disability claims.

Report System too Slow

Reports of accidents come in by mail. What chance is there to see about immediate treatment? To prevent infection? To set the broken bones before swelling sets in? Immediately to provide, in graver injuries, expert consultants to share responsibility with less experienced men? By the time the reports are received, the time for preventive surgery has gone by.

Let us take an example of how this failure to keep track of the injured leads to needless crippling. A chambermaid in one of the larger New York hotels sustained a Colles' fracture of the wrist. The fracture was immediately and properly set by a well known surgeon. The hotel then refused to give her further shelter, their rules not allowing sick servants to be kept on the premises. They sent her to a hospital, where she was informed that their rules prevented admission of ambulant fracture cases—an entirely proper regulation in itself—and so she wandered around for five weeks without any surgical supervision. By merest chance she came under the notice of the author in the accident ward of a hospital with which he is connected. Inquiries were made and she was promptly sent down to the casualty insurance company liable for her case. Her hands and fingers had stiffened and months of treatment were ahead of her if she was to regain any function whatever, this because that particular company had failed to keep track of her case and to bring her under timely and proper surgical after-care. Their own chief surgeon is a skillful man, but she was not brought to him in time.

The blame for this loss rested entirely on the claims department, or on the higher executives if they did not permit the claims department freedom in this matter. Yet, under the present system, with surgeons answerable to the claims department only, the knowledge of such losses is likely never to reach those in higher control, and recurrence of such errors will not be prevented in the future unless the prevailing system is changed.

The evils of the present system can be promptly and economically eliminated by the creation of a surgical department working in closest harmony and cooperation with the claims department, the heads of both departments being directly responsible to the chief executive of the company. Claims and medical departments will then act as checks upon each other, and the higher officers will know more about what is going on and where improvements may be inaugurated. The chief of such a surgical department should be a general surgeon in active practice. Without active hospital work, he would rapidly lose touch with progress in his specialty, fall behind, and soon cease to be of value to the company. The chief surgeon should have a reputation for high professional capacity and integrity among his own fellow specialists. It is safe to assume that such a man would be able to choose assistants of first rate professional caliber, who are to do the bulk of the routine work. These assistants should be men who have had hospital training as interns on the surgical service and should have good records for such service. They should be part time men. Being a full time man saps initiative, prevents a man from keeping up with his profession, keeps him from operative work and denies him the education of private practice. He has no opportunity for study or study travel. The assistant is the potential successor to his chief, hence he should be encouraged to improve himself so that he may in time qualify for the executive position. In the author's experience better work comes from several part time men of promise than from a fewer full time men. The same report has been made by others.

The chief object of the surgical department is to make sure that the injured man is receiving proper treatment from the hour of his injury until he is cured. This implies:

(1) *Reporting by telephone of accidents*, ascertaining exact nature of injury, authorizing transportation, diagnostic measures, form of treatment, and consultation with specialists.

(2) *Maintaining a daily follow-up system*, especially with reference to a reminder file regarding voluntary

motion at the earliest possible moment conducive with safety. Failure to start early motion at the right time is the greatest factor causing loss of function in fractures and hand infections.

(3) *Supervising of medical bills from outlying districts.*—The outside surgeon must render a concise statement of the original injury, the treatment and course of cure, together with the final result. The company paying him is entitled to a knowledge of these facts.

(4) *Analyzing of results.*—Cases of preventable disability to be subject of weekly or fortnightly conferences with claims and executive departments to ascertain means for correction of underlying causes.

Educational Measures Employed

I.—Surgical information should be disseminated for the guidance of claims departments, generalizing procedure in given conditions, as

(1) *Every fracture is to be regarded as an emergency and should be reduced as soon as possible.* (Reduction is infinitely easier before swelling takes place than after the lapse of even a few hours.)

(2) *Compound fractures may often be converted into simple fractures* if proper surgical treatment is applied within six to eight hours from the time of injury. It is recommended that Thomas splints be used in transporting patients suffering from fractures of the thigh and leg from plant to hospital. In the American Expeditionary Forces laymen were readily instructed in the proper application of Thomas splints and the positions they obtained were often so satisfactory that in a large percentage of cases further correction was unnecessary.

(3) *So-called contusions of the hip should be x-rayed.* Patients have been known to walk (limp) even a mile or two after fracture, and for this reason have been allowed to go months without diagnosis or treatment.

(4) *Infection of the hand* can often be prevented by prompt application of tincture of iodin. The experience of Mock with the mail order department of Sears, Roebuck & Co. shows what can be done in this direction by furnishing each desk with a small bottle of iodin, and a clearly worked out card of printed instructions. By such simple means as this the reduction in finger infection was more than 80 per cent. *Early diagnosis* minimizes the ravages of hand infections. Kanavel's textbook may be followed implicitly.

(5) *Divided tendons. In wounds of the fingers, the palm, or near the wrist* divided tendons can be diagnosed by requesting the patient to open and close the hand. Failure of complete motion indicates the necessity for immediate surgical attention. It not infrequently occurs that in cases of small incised wounds the physician merely sutures the skin and fails to recognize the more important injury to the underlying tendons.

II.—*Information may be supplied to employees* regarding certain common injuries and infections and what they mean, what surgery holds out to them—what they may expect; what risks they run from self-treatment or neglect. These pertinent matters can be printed in bulletin form to be posted at conspicuous points in factories and offices.

III.—*Education of employers* should include: what surgical neglect costs them; what surgical care saves them. A few typical examples will drive home the argument that nurses cannot replace doctors in treating minor injuries. The loss of a few fingers every year more than offsets this saving in salaries.

STATISTICAL REVIEW OF DISABILITY IN THE WORKMEN'S CIRCLE

By GEORGE RUBIN, Statistician, and JOSEPH BASKIN, General Secretary, New York City

THIS article is based upon data reached by a careful study of the experience of the Workmen's Circle through sick benefits paid to its disabled members. The Workmen's Circle is a fraternal organization counting about eighty-two thousand members and 642 branches distributed throughout the United States and Canada.

From the very nature of its name it is clear that this organization consists chiefly of workmen among whom it also counts about 10 per cent of business men and 1 per cent of housewives who also occupy a prominent place in relation to rates in the drawing of sick benefits.

According to the nature of the work the membership has been divided into twenty-one classes of occupation, including housewives and the class termed "Other Occupations," which includes those who cannot be separately classified because they constitute a small fraction of 1 per cent of the entire membership and also because in some cases the occupations are not known. From this classification is excluded a group of housewives belonging to as what is known class Number 3, because the members of this class are entitled to life insurance only and not to sick benefits. For the purpose of this analysis we are confining ourselves only to members insured against disability.

Provided that the nature of the cause of disability is the same, this organization pays benefits during three consecutive years and only for a period of fifteen weeks during each year at a rate of $6.00 per week during the first year and $3.00 during the second and third years.

According to our records about 97 per cent of the disabled drew benefits from one to fourteen weeks in one year, while only about 3 per cent drew for the full fifteen weeks, although it may be possible that some of the latter were disabled for a longer period, but owing to the fact that the percentage of such cases was very small, their effect on the disability calculations is negligible. Sick benefits are paid for not less than a complete week, beginning with the day on which the disability is reported. Because no benefits are being paid for a fraction of a week no records of disability of such durations are kept, but this defect is fairly counterbalanced by the inclusion into the period of our calculation the two epidemic years of 1918-19, which considerably increased the number of disability cases.

Age and Disability

The result reached by research covering a period of four years (1916-1919) is shown in Table I.

The average annual number of disability days begins with 2 for the age group of 18-19 and increases gradually

TABLE I.- ANNUAL AVERAGE NUMBER OF DISABILITY DAYS PER MEMBER AND PER DISABLED MEMBER OF EACH CLASSIFIED FIVE YEAR AGE GROUP

AGE GROUP	Total No. of Disability Days	Total No. of Members Affected	Total No. of Disabled Members	Annual Average No. of Disability Days per member	Annual No. of Disability Days per Disabled Member
18 and 19	2,065	1,029	107	2.01	19.30
20 to 24	82,299	25,703	3,880	3.20	21.21
25 to 29	209,538	57,967	9,585	3.61	21.86
30 to 34	241,185	65,771	10,725	3.67	22.49
35 to 39	173,362	44,171	7,097	3.92	24.44
40 to 44	101,122	20,747	3,739	4.87	27.04
45 to 49	39,928	6,973	1,329	5.73	30.04
50 to 54	8,337	1,713	288	4.87	28.94
55 to 59	1,071	209	38	5.12	28.18
Total	858,907	224,283	36,788	3.83	23.34

TABLE III.- RELATIVE DISABILITY RESPONSIBILITY OF EACH CLASSIFIED FIVE YEAR AGE GROUP

AGE GROUP	Total No. of Members	Per Cent of total Membership	Total No. of Disabled Members	Per Cent of entire Membership	Total No. of Disability Days	Per Cent of entire Membership
18 and 19	1,029	0.46	107	0.29	2,065	0.24
20 to 24	25,703	11.46	3,880	10.55	82,299	9.58
25 to 29	57,967	25.85	9,586	26.05	209,538	24.40
30 to 34	65,771	29.33	10,725	29.15	241,185	28.08
35 to 39	44,171	19.69	7,097	19.29	173,362	20.18
40 to 44	20,747	9.25	3,739	10.16	101,122	11.78
45 to 49	6,973	3.11	1,329	3.61	39,928	4.65
50 to 54	1,713	0.76	288	0.79	8,337	0.97
55 to 59	209	0.09	38	0.11	1,071	0.12
Total	224,283	100.	36,788	100.0	858,907	100.0

until it reaches a maximum of 5.73 for the age group 44-49. In the group 50-59 there is some variation. Both of these constitute only about 0.8 of 1 per cent of the membership and therefore are not of a very considerable importance in the relation to calculations.

TABLE II.- PER CENT DEVIATION OF DISABILITY DAYS OF EACH INDICATED AGE GROUP FROM AVERAGE NUMBER OF DISABILITY DAYS FOR ALL AGES (Average disability days for all ages - 100)

AGE GROUP	Per Member: Average No. of Disability Days	Per Member: Per-Cent Deviation from Average of all indicated age groups	Per Disabled Member: Average No. of Disability Days	Per Disabled Member: Per-Cent Deviation from Average of all indicated age groups
18 and 19	2.01	-47.52	19.30	-17.31
20 to 24	3.20	-16.45	21.21	- 9.12
25 to 29	3.61	- 5.74	21.86	- 6.34
30 to 34	3.67	- 4.17	22.49	- 3.64
35 to 39	3.92	+ 2.35	24.42	+ 4.63
40 to 44	4.87	+27.15	27.04	+15.85
45 to 49	5.73	+49.61	30.04	+28.71
50 to 54	4.87	+27.15	28.94	+23.99
55 to 59	5.12	+33.68	28.18	+20.63
Average, all age groups.	3.83	-- --	23.34	-- --

The purpose of Table II is to show the influence of the age as a factor upon disability. On the 100 per cent basis, the percentage of deviations up to the group of 30-34 is negative, that is, the average number of disability days of each of those groups is less than the general average. From the group 35-39 the deviations are positive, *i. e.*, the average number of disability days per member of these groups is more than the general average. The general number of disability days per member is probably to be looked for in the ages 34-36 because of the fact that the average age of the entire membership of this organization is 33. Charts I and II set up more clearly the illustrations contained in Tables I and II, respectively.

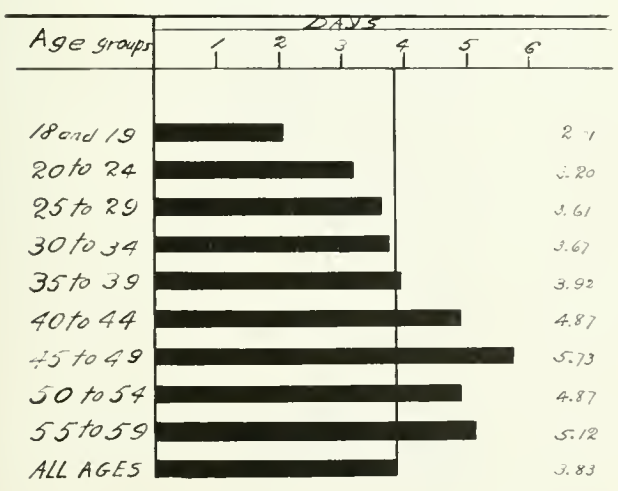

Chart I. Average number of disability days per member, all occupations, by age groups.

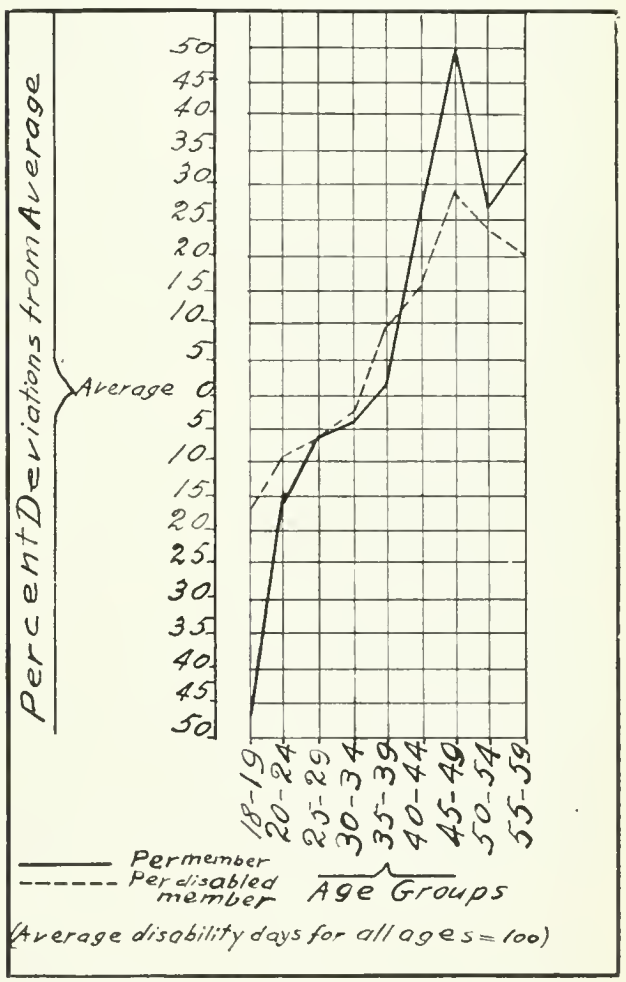

Chart II. Per cent deviations of disability days of indicated age groups from the average number of disability days for all age groups.

TABLE IV.- ANNUAL NUMBER OF DISABILITY DAYS PER MEMBER AND DISABLED MEMBER OF EACH OCCUPATION OF ALL AGE GROUPS (16-59)

OCCUPATION	Total number of members concerned	Total number of disabled members	Total number of disability days	Annual number of disability days per member	Annual number of disability days per disabled member
Housewives	2,001	745	17,248	8.62	23.14
Laborers	11,337	3,488	67,074	5.92	19.23

Shoe Makers	4.70	+ 19.0	22.13	+ 7.8
Pressers	4.63	+ 17.2	22.04	+ 7.4
Businessmen	4.25	+ 7.6	20.91	+ 1.9
Cigar Makers	4.16	+ 5.3	20.90	+ 1.9
Clerks	3.81	- 3.5	22.14	+ 7.9
Leather Workers	3.74	- 5.4	20.11	- 2.0
Weavers	3.66	- 7.3	19.86	- 2.2
Operators	3.52	- 10.9	19.75	- 3.8
Tailors	3.52	- 10.9	20.90	+ 1.8
Printers	3.39	- 14.2	19.61	- 4.4
Furriers	3.34	- 16.4	19.92	- 2.9
Cutters	3.18	- 19.5	20.65	- 0.6
Other Occupations	1.78	- 54.9	20.92	- 1.9
Average, all occupations	3.95	- -	20.[illegible]	- -

We have attempted to show in Table III the relative disability responsibility by comparing it with the strength of the various age groups. In the groups up to 30-34 the responsibility is less than the strength (columns two and six) because the disability responsibility is less than the average for those age groups, while for the others the disability responsibility is more than the strength.

The variation of the percentage of disabled members is approximately the same as the percentage of the membership.

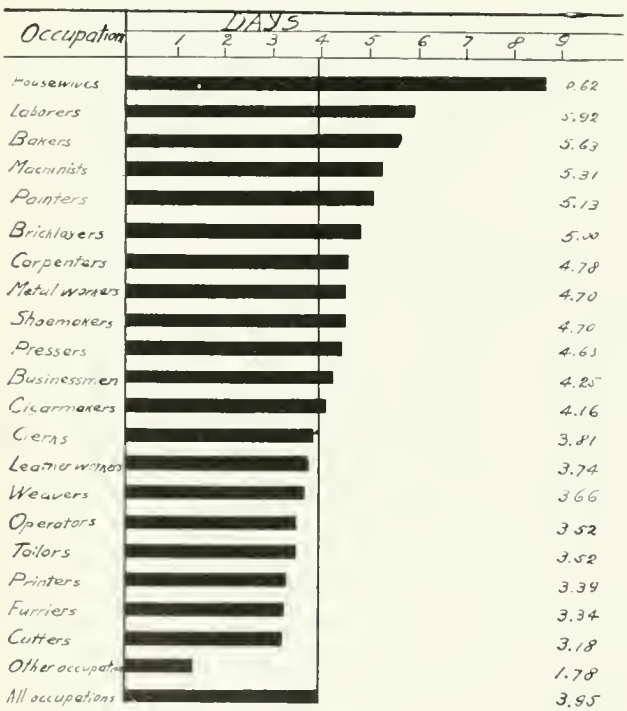

Chart III. Average annual disability days for each occupation, all ages.

Disability by Occupation

Occupation is undoubtedly an important factor in disability. Table IV shows the result reached by researches covering a period of seven years (1913-1919) and is supplemented by Chart III. Disability classed according to occupation is shown in order of magnitude, beginning with the greatest average and ending with the smallest. It appears that housewives constitute the highest annual average of disability days per member, a fact which cannot be explained by our records.

The deviation from the general average which is a measure of the effect of each occupation upon the health is shown in Table V. A negative deviation means a lesser effect upon the health of the group, while a positive deviation shows a greater and more detrimental effect, the standard of comparisons used in all occupations and ages being 100 per cent.

Chart IV. Per cent of disabled members of each classified occupation, all age groups.

Table VI shows how far each occupation is relatively responsible for disability. A comparison of columns two

TABLE VI.- RELATIVE DISABILITY RESPONSIBILITY OF EACH CLASSIFIED OCCUPATION (ALL AGE GROUPS)

OCCUPATION	Total number of members	Per cent of total membership	Total number of disabled members	Per cent of entire membership	Per cent disabled members of each classified occupation	Total number of disability days	Per cent of entire membership
Housewives	2,001	0.58	745	1.12	37.2	17,246	1.27
Laborers	11,337	3.29	3,488	5.25	30.7	67,074	4.93

Cigar Makers	5,904	1.71	1,175	1.77	19.9	24,563	1.80
Leather Workers	3,483	1.01	647	0.97	18.6	13,013	0.96
Weavers	6,872	2.00	1,265	1.91	18.4	25,123	1.85
Operators	38,426	11.16	6,847	10.32	17.8	135,254	9.93
Clerks	18,256	5.30	3,171	4.78	17.4	70,217	5.16
Printers	2,828	0.82	489	0.73	17.3	9,597	0.70
Tailors	69,182	20.08	11,641	17.54	16.8	243,341	17.87
Furriers	3,798	1.10	637	0.96	16.8	12,698	0.93
Cutters	8,099	2.35	1,245	1.88	15.4	25,725	1.89
Other Occupations	36,206	10.52	2,947	4.44	8.1	64,596	4.74
Total	344,467	100.0	66,352	100.0	19.3	1,361,626	100.0

and seven shows that the relative proportion of the two columns varies, for in some occupations the percentage is higher than the strength, which means more detriment to the health, while in those occupations where the strength is higher it means more detriment or risk. The percentage of disabled in column four of this table is approximately the same as the disability days. Column

TABLE VII.- ANNUAL NUMBER OF DISABILITY DAYS PER DISABLED MEMBER FOR EACH PARTICULAR SICKNESS (ALL AGES AND OCCUPATIONS)

NATURE OF SICKNESS	Total number of disabled members	Per Cent of entire membership	Total number of disability days	Per Cent of entire membership	Average number of disability days per disabled member	Total sick benefit paid for each disease	Per Cent of entire membership
Influenza	15,909	23.97	193,263	14.19	12.15	165,654	14.73

Total	66,096	100.0	1,361,626	100.0	20.0	1,125,789	100.0

six shows the percentage of disabled members of each occupation and Chart IV graphically illustrates the result

Disability by Disease

In the section covered by Table VII is shown the effect of various diseases upon the members and the extent of disability. The percentage of disabled appears to be higher than that of any other group of cases due to accidents and lower in serious diseases. The percentage of disability days varies in no proportion with the number of disabled members. The average number of disability days per member varies according to the seriousness of the disease.

An attempt is made in Table VIII to show the average percentage of disabled members of the indicated occupations according to the various diseases. It is to be noted that the highest percentage of disabilities occurs under

TABLE VIII.- AVERAGE ANNUAL LIABILITY TO DIFFERENT DISEASES OF EACH INDICATED OCCUPATION

This table contains only those diseases which affected one per cent or more of one or several occupations.

OCCUPATION	Number of members concerned per year	Per cent of diseased members of each indicated occupation for each indicated disease: Bronchitis	Tuberculosis	Diseases of digestive organs	Tonsilitis	Heart Disease	Infection (Surgical)	Accidental injuries	Rheumatism	Influenza
Bakers	286	2.0	1.7	2.2	1.6	-	4.2	6.3	2.3	6.5
Bricklayers	422	1.4	-	2.4	1.2	-	4.0	5.5	2.0	5.4
Businessmen	5,365	1.0	-	1.8	1.0	-	2.2	3.9	1.5	4.7

Tailors and Operators	15,273	1.0	1.0	1.7	1.1	-	2.0	2.2	-	4.6
Weavers	982	1.2	-	1.6	-	-	2.2	2.3	1.7	4.1
Other Occupations	5,172	-	-	-	-	-	-	1.4	-	2.0
Average	49,210	0.99	0.95	1.68	1.08	0.14	2.43	3.66	1.11	4.62

the classification of "Accidental Injuries," and that next in importance is the classification "Infections, Surgical." These two causes account for the greater percentage of the disabilities that affect the hard workers, involving close to 10 per cent of the groups made up of this class of members.

It is remarkable that the needle trades, contrary to the general expectation, were the least afflicted by tuberculosis, while the bakers and shoemakers furnished the greatest percentage of its prey. Under the class "Influenza" will be found the greatest percentage of disabled members, which fact is due to the epidemic years of 1918 and 1919.

FOR VICTIMS OF INDUSTRY

Industrial rehabilitation work, provision for which was made by a recent act of Congress, will be under the direction of Lewis H. Carris, former assistant commissioner of education in New Jersey. Mr. Carris will have supervisory control of the work as it is carried on by state boards of vocational education. He has been employed by the Federal Board since 1917. This Bureau makes possible reclamation on a large scale and proposes for industry the same restoration worked out for men disabled in military service.

SANITATION AND PELLAGRA INCIDENCE

The study instituted in the Spring of 1916 on the relation of various factors to pellagra incidence has just been completed and final report made in *Public Health Reports*, July 16, 1920. The survey of seven respective mill villages failed to reveal any consistent correlation between factors of sanitary importance and the incidence of pellagra, this result affording no support for the view which has been quite widely entertained in this country that pellagra is "an intestinal infection transmitted in much the same way as typhoid fever."

The new Officers of the National Safety Council, elected at the Ninth Annual Safety Council held in Milwaukee, September 27 to October 1, 1920.

NEW OFFICERS OF NATIONAL SAFETY COUNCIL

The National Safety Council, in its Ninth Annual Session, held in Milwaukee recently, elected to office the following men, reading from left to right: W. H. Frater, treasurer, National Safety Council; C. W. Price, general manager, National Safety Council; second vice-president, L. A. DeBlois, manager of Safety Section, E. I. du Pont de Nemours & Co., Wilmington, Del.; first vice-president, W. H. Cameron, secretary-treasurer, Workmen's Compensation Service Bureau, New York City; president, Charles P. Tolman, chief engineer, National Lead Company; third vice-president, W. E. Worth, assistant manager, Industrial Relations Department, International Harvester Company; fourth vice-president, J. A. Cartel, safety engineer, Carnegie Steel Company; Sidney J. Williams, secretary and chief engineer, National Safety Council.

On these men devolves the exacting task of carrying forward a movement which has been characterized by a phenomenal growth and a dynamic influence in an ever widening field of welfare work. The National Safety Council has succeeded in reducing hazardous industries to places of safety, in substituting a sane knowledge of conditions for haphazard chance, in popularizing the steady workmen with rational self-control instead of the dare-devil type who takes unnecessary risks, and in arousing among the several industries a competition for conservation replacing a needless waste of manpower.

In accomplishing these results the National Safety Council has furnished conclusive demonstration that it is necessary not only to put a plant in order, but the work of the safety man needs to be supplemented by human engineering; that accidents do not *happen*, but are the result of certain combinations of causative factors and follow curves that can be demonstrated for each industry; that certain types of men are prone to accident, just as men of certain physique are susceptible to disease; that no program of safety is adequate that does not consider all factors and serve equally the interests of the management and the men.

Educational measures on a large scale have been necessary with methods specially adapted to effect these changes. The laboratory has yielded its service, psychology has been properly applied, and scientific training of managers has been provided. The ultimate scope of the movement is limited only by the degree of popular interest and cooperation the Council is able to maintain.

AMERICAN HOSPITAL ASSOCIATION

The twenty-second annual convention of the American Hospital Association held on October 4 to 8 in Montreal was inspirational both in recent achievement and in prophetic elements as shown by the activities projected. The hospital as the center of the health activities of the community was the view elaborated in the administration problems discussed by Dr. Malcolm T. MacEachern, and in the public health program of the future as outlined by John A. Lapp. In all discussions the hospital was seen as the coordinating factor between the civil, economic, social, and scientific phases of community health activities.

The obligation of the hospital, first and foremost to the patient, formed the special burden of the paper by Dr. Frank Billings, president of the American Conference of Hospital Service. The extension of the scope of hospital service was nowhere in greater evidence than in the discussion of dispensary and out-patient service, led by Asa S. Bacon, superintendent of the Presbyterian Hospital, Chicago. The Bureau of Information of the American Association of Hospital Social Service Workers was especially well planned to supply consultants an organization training and education in departmental efficiency.

Officers were elected as follows: Louis R. Baldwin, M.D., president, University Hospital, Minneapolis, Minn.; George O'Hanlon, M.D., president-elect, superintendent, Bellevue Hospital, New York City; M. T. MacEachern, M.D., first vice-president, superintendent, General Hospital, Vancouver, Can.; L. G. Davidson, M.D., second vice-president, Baptist Memorial Hospital, Memphis, Tenn.; Miss Alice M. Gaggs, third vice-president, J. M. Norton Memorial Infirmary, Louisville, Ky.; Asa S. Bacon, re-elected treasurer, superintendent, Presbyterian Hospital, Chicago; A. R. Warner, M.D., re-elected secretary, American Hospital Association.

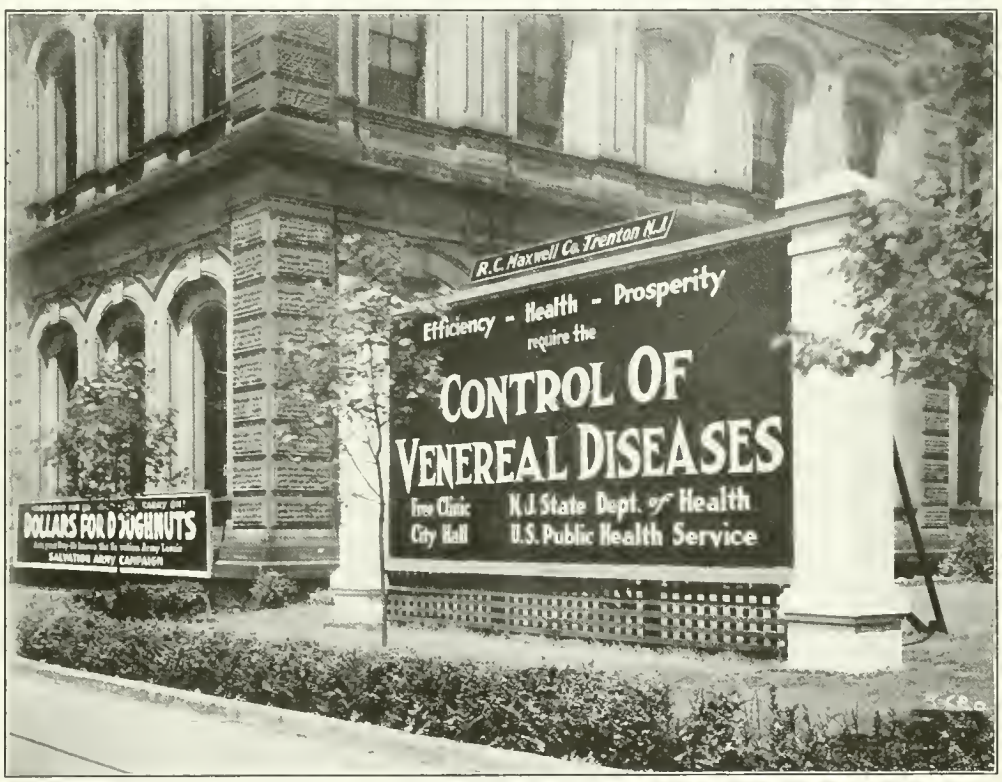
NEW JERSEY VENEREAL DISEASE BUREAU USES NOVEL PUBLICITY METHODS

By ALEC N. THOMSON, M.D., Director, Medical Department, American Social Hygiene Association, New York City

METHODS of publicity used by the Bureau of Venereal Disease Control of the State Department of Health of New Jersey include the most up to date devices for utilizing the "eye-gate" of its constituency. The publicity campaign consisted of the posting of educational placards, the distribution of educational pamphlets, the giving of educational lectures, accompanied, where possible, with approved motion pictures or stereopticon pictures on sex hygiene, and the exhibition of posters. It was realized that the education of the public in its broadest sense is a phase of the work of controlling this great menace to public health that brings the greatest returns, and to this end the organizations were enlisted to assist in the work by concentrating on the educational phase.

Subsequent to the usual conventional publicity campaign, the Bureau decided to branch out. Carefully worded advertisements were placed on four large billboards using "preferred space" in prominent locations in the city of Trenton.

Simultaneously the following innovations were tried: the placing of three cards about venereal disease in every street car in Trenton; the showing at every performance in each of twelve motion picture houses of Trenton of two or three slides about the campaign; the placing of a conspicuous notice in the two leading newspapers at Trenton, giving all necessary information in regard to the city clinic.



Example of advertising used in the venereal disease campaign, New Jersey.

Having demonstrated to their own satisfaction that the results of the intensive campaign in Trenton justified the employment of similar measures in other communities, such campaigns have been inaugurated in Elizabeth, Plainfield, and other Jersey cities. A state wide distribution of billboards has also taken place, three large signs having been painted along the lines of the Pennsylvania Railroad between Elizabeth and Bound Brook. These attract the attention of both the national traveling class who pass frequently between Philadelphia and New York, and of the suburban and local residents in the New Jersey towns along the way. The posters and billboards include a slogan or appeal in some terse wording that can be read by him who runs, and a reference to the free clinics maintained by state departments of health in conjunction with the United States Public Health Service in several of the larger population centers of the state.

The results of the New Jersey campaign can be traced in the tabulations, by months, that have been made by the Department of the number of Wassermann blood tests and examinations of Gonococcus smears made in the state laboratory. For the entire state the figures show a gradual and steady increase, indicating the growing interest of the medical profession in proper treatment and diagnosis and of their willingness to make use of the state facilities. The 1919 figures compiled separately for Trenton, Camden, and Elizabeth show, respectively, a rapid increase, a slight increase, and a stationary total. These variations are due, say the representatives of the Bureau, to the fact that the vigorous publicity campaign was started in Trenton, the state capitol, a moderate one was carried out in Camden, and practically nothing was done in Elizabeth up to that time. Further, the average daily attendance and the total weekly attendance at the Trenton venereal disease clinic rose steadily during the period of the intensive campaign. A similar trend is noticeable in the totals for cases of venereal disease reported to the health authorities.

The most recent publicity device that has been used in the state is a series of animated pictures that has been shown in the various cities of the state. These pictures

are thrown on a glass plate in such a way that a portion of the first picture remains while another portion dissolves into a second picture illustrating an allied phase of the subject.

STRENGTH TESTS IN INDUSTRY

A report is made in *Public Health Reports* under date of August 13, 1920, describing the results of strength tests as applied to industrial workers. Fluctuations in strength from day to day and variations during a single day are important as affecting the industrial efficiency of the worker, and a study of such variations should lead to information concerning the factors which influence the physical conditions. The deductions drawn from these studies are summarized as follows:

(1) Fields of usefulness for strength tests are seen in (a) physical classifications, to aid in selecting operatives for particular jobs; (b) as criteria of physical condition in connection with the relationship of physical condition to industrial efficiency (c) as criteria of fatigue.

(2) The method of testing the strength of industrial workers is described in detail.

(3) Evidence is presented showing that with males laborious operations tend to develop approximately equal strength among the workers therein; in other words, there is a "standard" strength for each job. A table of the strengths associated with the various operations studied is given.

(4) Male workers at very light operations are shown to have, in general, the average strength for adult males. A single group, made up of men with various disabilities and engaged in a very light sitting operation, had an average strength markedly less than the mean for healthy adult males.

(5) Evidence is offered that within individual groups of males the stronger workers are likely to be more efficient industrially than the weaker.

(6) The occurrence among male workers at laborious operations of individuals whose strength is much less than the standard for the job, and somewhat below the usual figure for healthy adult males, is assumed to be indicative of "staleness" due to persistent overexertion. Workers giving signs of "staleness" show greater variations in the distribution of strength among the muscles in successive tests than do normally strong operatives.

(7) The question of the genuineness of poor strength showings is discussed and evidence is given that it is more difficult to make deliberately an inferior test than to put forth full strength, and also that the variations in successive tests would necessarily be wider if the tests were fraudulent than are seen in the poor series here under examination.

(8) That physical condition, as indicated by the strength showing, tends to bear a definite relationship to the industrial efficiency as expressed in output is shown by comparisons of day-to-day records of various male workers.

(9) Observations are given showing that there is a definite tendency for the strength of all the male workers in a single environment to fluctuate similarly from day to day. The conclusion is drawn that external factors are operative in determining strength, and that these act on all the workers alike. Among these the temperature at which the work is carried on suggests itself as important. There is evidence that persistent exposure to temperatures above 30° C. (86° F.) is unfavorable to strength. Relative humidities between 70 and 80 per cent appear to favor high strength showing. Other climatic influences have not been demonstrated to be operative. There is some suggestion that psychic influences, such as the arrival of pay day, may be operative. Since strength correlates with productiveness, the analysis of these external factors promises to be significant.

(10) In general, strong male workers show less fatigue than do weaker workers. This holds both for workers regardless of the nature of their work and for the strong and weak groups within particular operations.

(11) Evidence is given indicating that the impairment of physique due to exhaustion may be so severe as to require considerable time of rest for recovery to normal strength.

(12) There is evidence that the effects of fatigue are persistent, in that they tend to appear on the day following a day of fatigue. Severe fatigue is more likely to show this persistent effect than is mild fatigue.

(13) Days of poor physical condition are more likely to be followed by days of fatigue than are days of good condition, or days on which no demonstrable fatigue appears.

(14) There is no evidence that the strain of night work in an eight hour shift, changing every two weeks, impairs physique. A permanent night shift, working twelve hours nightly five nights in the week, averaged 15 per cent lower in strength than the day shift doing precisely similar work; but the evidence is insufficient to decide whether or not this poorer showing was actually due to the night work.

(15) Women operatives show a gradation of strength corresponding with the laboriousness of their work; the actual strength showing is, however, regularly less than would be anticipated in manual workers.

(16) Women employed at tasks requiring mental alertness or close concentration make better strength showings than those engaged in a routine manual toil, even though the latter be relatively heavy. A corresponding relationship is not apparent among male workers.

(17) There is evidence that among women, as among men, external factors influence the strength showing. The workers in a similar environment tend, as a group, to very in the same direction from day to day.

(18) Among women, as among men, demonstrable fatigue is more manifest in weaker workers than in stronger. The most pronounced indications of fatigue are presented in an operation requiring close concentration and carried on in a disagreeable environment.

ANTHRAX SERUM CUT OFF

The decision of the United States Government to discontinue the preparation of anthrax serum constitutes a menace to the community, according to Douglas Symmers, M.D., director of laboratories of the Bellevue Hospital, New York, which is the largest individual user of this therapeutic agent. The appropriation for that work was cut off by Congress on July 1 last.

The preparation of anthrax serum is both difficult and dangerous and should be left to highly trained hands. If health authorities of the states are to provide their own serum, they will need to be granted ample means, financial and otherwise, in order to provide hospitals and practicing physicians with plenty of anthrax serum.

INDUSTRIAL FEATURES OF BRITISH CENSUS

Certain new industrial inquiries will be introduced in the taking of the next official British census on the last Sunday in April, 1921. It is planned to make inquiries concerning the number of people engaged in occupations and in various industries and the movements of the population in going to and from work. These statistics are designed to assist in the handling of various educational, transportation, and general labor questions. It is further intended to ask questions on the matters of dependency, pensions, health insurance, and unemployment insurance. It is said that a provisional return will probably be available by the middle of June.

The census bill now before the British Parliament provides permanently for the taking regularly of a census. Heretofore separate authority has been required every ten years when a new census was to be taken. It is also possible, under the provisions of the new bill, to arrange for the taking of an interim quinquennial census. It will be determined in 1926 whether a census will be taken at that time.

It is considered that these data, not having heretofore been available, account for some of the inadequacies of programs designed to meet the needs of industrial communities.

THE NATION'S HEALTH

Public Health and Public Welfare, Administrative Medicine, Organized Health Service

C.-E. A. Winslow, Dr. P. H., *Editor*

PUBLIC HEALTH AND INSURANCE

AMERICA has always drawn largely upon England for inspiration and leadership in the field of public health. Lemuel Shattuck sat at the feet of Southwood Smith and Edwin Chadwick, although the Report of the Massachusetts Sanitary Commission which he prepared in 1850 was a document which in its own right ranks with the classics of British sanitary literature. Even today, however, there is a depth of scholarship and a breadth of statesmanship in the treatment of public health problems by the leaders in English public health which is rarely equaled on this side of the ocean. We are in such haste to obtain definite and immediate results, and often so successful in obtaining them, that the leisure for thinking out fundamental relationships is rare and the finished literary presentation of the fruits of such thought is even rarer.

Sir Arthur Newsholme's recent book on Public Health and Insurance,[1] which embodies the principal addresses delivered by him during the first year of his service as Lecturer on Public Health Administration at Johns Hopkins University, is therefore a peculiarly welcome contribution to the complex subjects with which it deals. The author has for thirty-five years been a leader in the practical tasks of preventive medicine in England and for eleven years the Principal Medical Officer of the Local Government Board. He has presented in these American addresses the mature and considerate judgment, in regard to public health policies, of a wise and constructive idealist of unusual practical experience; and the book is one that will prove of vital interest, not only to official public health workers but to physicians in general and to students of social reform of every kind and class. The author's description of recent English administrative developments in the control of tuberculosis and venereal disease and in infant welfare work—during the past four years central grants for special maternity and child welfare work having increased twelve-fold, the number of health visitors more than doubled, and the number of maternity and child welfare centers having increased five-fold—will be inspiring to students of public health as a profession; but his views in regard to the broader principles of the public health movement as a whole and its relation to the medical profession are of even wider importance.

Sir Arthur's first thesis, if one may attempt to concentrate the essence of a whole volume into a few lines, is the importance of sickness as a factor in poverty. He does not, of course, deny the inverse relation. Sickness and poverty form a complete and vicious circle. He does, however, urge with unusual force the argument, upon which Chadwick and Simon based the foundations of the modern public health movement eighty years ago, that sickness is not only a far larger factor in destitution than is commonly realized but that it is also a factor peculiarly amenable to preventive treatment and therefore deserving the immediate attention of the social reformer. He believes that in addition to all that has been accomplished in the past "it will be easy within the next ten years to reduce the death rate by one-third of its present amount, given systematic and adequate action on the part of public health authorities and an effective educational propaganda among the general public." There will never be complete success in attaining these ends, however, "until means are discovered for training and enlisting every medical practitioner as a medical officer of health in the circle of his private or public practice, and of securing his services not only in the early and prompt detection of disease, but also in the systematic supervision during health of the families under his care, and in advising them as to habits or methods of life which are inimical to health."

The second lesson to be drawn from these addresses is the danger of following false principles in the organization of administrative machinery for the prevention of disease. In particular he condemns "the *ad hoc* vice,"—"the inveterate tendency to create a new authority when any new work was inaugurated, this authority then fulfilling all purposes for a special portion of the community and thus necessarily duplicating the staffs of other departments of local or central government." He furnishes strong evidence to show the harm that has resulted through the separation of the medical service furnished under the Poor Law Authorities from the scheme of general public health administration; and he is convinced that the same mistake has been made in the National Insurance Act of 1911, which he condemns, in its present form, as economically unsound, medically reactionary, and worse than useless as a factor in the prevention of disease. Insurance, he believes, is one problem; the provision of necessary medical care another. The latter function should be related to the general public health program rather than to the insurance of a special class of the population. "The treatment and the prevention of disease cannot administratively be separated without injuring the possibilities of success of both."

From these premises it follows that the future success of the campaign for the control of preventable disease, and the destitution which it causes, must depend on the development of state medicine. By this term Sir Arthur means, of course, no arbitrary and Utopian revolution in medical practice but the orderly evolution of such

1. Johns Hopkins Press, Baltimore, 1920.

present tendencies as are seen in the development of school medical service, and public dispensaries, sanatoriums, and hospitals of many types.[2] The task of reorganizing medicine, on a communal basis is indeed, he estimates, half accomplished in England at the present time. "Already the Government pays one-half of local expenditure on a large program of maternity and child welfare work, one-half of the expense of local tuberculosis work, and three-fourths of the expense of local work for the diagnosis and treatment of venereal disease and for propaganda concerning these." The full control of disease which medical knowledge might accomplish will not, however, be realized "until every medical practitioner is trained to investigate each case of illness from a preventive as well as from what is often rather a pharmaceutical than a really curative standpoint, until a communal system of consultant and hospital service independent of any insurance system is made available for all needing it, and until every medical practitioner is related by financial and official ties to this communal system." The two fundamental objects which should always be kept in mind in planning for the socialization of medicine have seldom been more clearly stated than in the following sentences: "One essential item will be the substitution for fees during sickness of an annual payment to private practitioners by each family for supervising its members in health, for inquiry into their industrial and domestic life so far as it contains elements inimical to health, and for giving preventive more than curative advice. The second and most urgent element consists in the organization of hospital and consultative expert services for all, which, while greatly increasing each patient's prospect of prompt recovery, will enable the general practitioner to escape from the soul-destroying inefficiency of unaided medical practice."

2. The bill introduced into the last New York legislature and to be reintroduced at the next session (discussed in MODERN MEDICINE for April, 1920) is apparently the sort of measure which is contemplated.

In regard to the great obstacle which tends to retard the development of social medicine in America at the present time—the fear of political corruption and inefficiency—Sir Arthur takes a courageous and hopeful stand. He vigorously denounces the effects of selfish interests and timid parsimony in public administration of sanitary affairs and appeals with eloquence for the watchful alertness of the individual citizen to rebuke such tendencies. If, however, "democracy is to be real,—and we have no sound, practicable alternative to it,—evidently the representatives of the people must be masters of the administration; and English policy has never wavered on this point." These matters he regards as belonging to the direct iniative of the people and would presumably not approve of the rather general tendency in this country to protect health administration from direct contact with the primary source of legislative authority through delegation of power to expert commissioners and executive officers. "All substitutes for government of the people by the representatives of the whole population," he believes, "are open to objection. They do not contain within them the elements of permanence. If there is a corrupt council, the remedy is not in its suppression by an independent executive. Such an executive is the abrogation of popular government."

The difference between conditions in England and the United States, in this and other respects, may materially modify the application of these views in America. England has built up her public service far more solidly than we have done. On the other hand, the success of private initiative in this country in the development of industrial medicine, public health nursing, and hospital and dispensary service through private initiative indicates a special aptitude for constructive social progress along non-political lines. Yet here, as elsewhere, Sir Arthur Newsholme's experience and counsel will be of inestimable benefit in the difficult tasks of sanitary statesmanship.

EDITOR.

COMMON SENSE ABOUT CLIMATE

BY CHARLES HENRY LERRIGO, M.D., STATE BOARD OF HEALTH, TOPEKA, KAN.

LESS than a year before, in his far Eastern home, Dave had stood stripped to the waist, in a doctor's office while the spectacled man of science carefully sounded a bare chest and back. "It's what I was afraid of, lad," the doctor had said at last. "There's a spot on your lungs. But you're not in bad shape. A few months in the open in the Southwest will straighten you up, if you can arrange to get there."

Dave did arrange and when he boarded a westbound train he had a long, one-way ticket to Arizona. Although none too well supplied with money he worried but little over his finances, because his intentions were to do the same thing as he had been doing for some time—work. The day after he stepped from the train he found a job.

The above extract from a story just published in a magazine of wide circulation is representative of the popular impression that is conveyed by the literature that is served to the reading public of the United States in reference to conditions that are necessary in order to cure tuberculosis. It assumes that the doctor finds a spot on the lungs and that all that is then necessary is a few months in the open in the Southwest. The patient, who is none too well supplied with money, does not worry about his finances because his intentions are to work, and the day after he steps from the train he finds a job.

If such sentiments as these were promulgated only through the lay press, that would not be so utterly surprising because we can easily see in them the remains of medical teaching of a quarter of a century ago. Unfortunately, however, there is still a very general feeling among those members of the medical profession who have not made a special study of tuberculosis and do not give it special attention, that this method of treatment is really effective towards its cure.

Go to a representative gateway to the West and Southwest, such as Kansas City, any day in the year, and give attention to the travelers passing through the Union Station. You will need to watch only a short time to see passengers for Colorado, Texas, New Mexico, Arizona, or southern California who are so marked by the ravages of the white plague that the most casual observer is aware of their affliction.

They are traveling in day coaches, chair cars, and possibly tourist sleepers. Rarely do you see such patients enjoying the luxury of a Pullman coach. Persons who can afford expensive methods of travel can afford up to date physicians who know better than to advise such a disastrous journey. There are laws which provide that railroads shall carry such persons only if compliance has

been made with certain regulations that will serve to protect the traveling public, but it is rare that any effort is made to observe such laws.

I saw such a victim enter a car in which I was traveling. He was helped to a seat near the water cooler by two Redcaps, and sank into it quite exhausted. When he was rested, I took the vacant seat by his side in order that I might inquire how I could serve him, for I have as much sympathy for such a victim as I have indignation against his cruel advisers. He told me that he had been ill for a long time but had got along without a doctor. However, he was now on his way to a sanatorium of high repute operated by a fraternal organization in which he held membership. His only worry was that the sanatorium had notified him that he could not stay if he had reached an advanced stage of the disease.

He was so plainly marked for an early grave that there was not a passenger in that crowded car unconcerned as to his immediate welfare. Yet the cruel advice to "go West to a better climate" had led him into a terrible journey that could end only in disaster.

And yet he was not in the parlous plight of the common migratory consumptive, for at least he was consigned to an institution that would give him some care if not more than to arrange for his return journey. Think of the hundreds who go out in a vain quest for the land of robust health and golden prospect, only to find that to the sick and poverty stricken person it is nothing but an overcrowded, high priced, hard place where the responsiveness of the public has been dulled by too frequent appeals to its charity, and there are "no public institutions with free care for non-residents," and where the pangs of homesickness will add a bitter sting to the depression and distress of sickness and poverty.

No wonder that they die before the favored climate has given them a chance.

Why the Indigent Migrate

The National Tuberculosis Association has attempted to investigate the conditions under which a large number of the indigent migratory consumptives, whose migrations have carried them to certain of our health resorts in the Southwest, were induced to make the journey. It is found that out of 1,786 cases 738 had been advised to make the journey in search of health to these southwestern points by their physicians; and that, too, in spite of the fact that these persons sick with consumption had no financial resources, had no friends to receive them at their journey's end, and would be dependent for sustenance upon such work as they were able to secure when they arrived at the "land of promise."

Without bringing into discussion the possible advantages that certain climates may possess, it is now generally accepted by all authorities on the subject of tuberculosis that any climate is a good climate for recovery from the disease, provided that it can be enjoyed in comfort, the patient being protected by proper clothing and bedding, being supplied with a liberal amount of well selected food, and having all care and worry removed from his mind so that he may be able to enjoy both mental and physical rest while the processes of cure are being established.

With such acknowledged facts, it is most deplorable that the opinion is still almost universal among lay writers that the cure of tuberculosis demands a visit to the great Southwest, and that it is quite unimportant what the financial condition of the patient may be, since he undoubtedly will be able to support himself by his own labors once he is established in the ideal climate. If it is aggravating to have such sentiments voiced by lay writers, how much more exasperating is it to find medical men still giving expression to such opinions, and actually sending a large number of patients to a destination that will cut them off from home support, thus in very many cases virtually sending them to their doom.

Under these circumstances, it is interesting to read the warning that is sent out by the State of California to Eastern health seekers:

California Warns Eastern Health Seekers

Tuberculosis demands rest, food, fresh air, and peace of mind. This may not mean a change of climate.

California has no public institutions with free care for non-residents.

With funds to live for a year, come, but do not rely on finding light work for support.

The State Board of Health warns you, because it wishes to spare you homesickness and suffering from financial strain.

These statements are sent out over the signature of the Bureau of Tuberculosis, California State Board of Health.

It is also refreshing to notice that at the New Orleans meeting of the American Medical Association the following resolutions were adopted concerning migration of indigent consumptives:

WHEREAS, The National Tuberculosis Association, through investigation of its Committee on Indigent Migratory Consumptives, covering the last fifteen months, has found:

That there is a large migration of indigent consumptives to the Southwest in search of health;

That out of 1,786 cases, largely indigent or potentially indigent, reported from the Southwest in the last six month, 738, or 41.3 per cent, had been definitely advised to go there by physicians;

That this migration of indigent and potentially indigent consumptives is ill advised in that it causes much needless suffering and loss of life brought on by inadequate care, worry, homesickness, and lack of proper food, which are conditions too frequently experienced after arrival; and furthermore,

That this migration of this group is a menace to the public health, both during migration and after arrival, and is a financial drain and social burden to the communities to which the migration goes. Therefore, be it

RESOLVED, That in order to check this unnecessary and undesirable migration, physicians throughout the country be not only requested but urged *not* to advise their tuberculosis patients to migrate to the health resort states, unless such patients have sufficient funds to properly provide for their necessary care and comforts for at least one year.

It is to be hoped that accurate information may rapidly be spread among social workers, writers, and teachers of every kind, since it is so very important that the general public shall understand:

(1) That it is not necessary to leave home in order to be cured of tuberculosis.

(2) That in order to effect a cure of this disease it is absolutely necessary to stop work and secure perfect rest, both of body and mind.

(3) That if there is any advantage at all in the supposedly favored climates, which have been known for many years as health resorts for the cure of tuberculosis, that advantage is utterly nullified for anyone who cannot combine with it all the comforts of home, together with freedom from worry and work.

Uncorrected activities are essentially selfish and not infrequently they may be cruel and inhuman, but power once acquired may and should become an agent of great beneficence and does when united with those elements of character which make for constructive ends. Progress is away from purely selfish ends.—William A. White.

INFLUENCE OF MEDICAL PROFESSION ON LEGISLATION AND THE PUBLIC WELFARE*

By JOHN B. HAWES, 2ND, M.D., Boston, Mass.

IN A recent editorial in the *Boston Medical and Surgical Journal* the following statement was made: "The report of the Joint Committee in Legislation published in last month's issue of the *Journal* is discouraging to those who hoped for progressive action on the part of the legislature this year. It is discouraging to realize how little influence, except in a negative way, the medical profession exerts through the Joint Committee. While no backward step has been taken, the record is one of complete failure to gain any step forward."

What weakness of influence is exhibited by the medical profession in matters of legislation is not to be attributed to the principles for which they stand nor to the motivation of their activities.

Their programs have lacked the drive which invariably attaches to self-interest, and the measures they have employed for affecting legislation have been vague, intangible, and for the most part addressed after the mind of the legislator was all set for action, and not open to change.

If as a profession physicians are to achieve a potent, persistent pull for constructive legislation, they must evolve an organization which politicians will need to notice and which both the people and their representatives will accord a confidence they do not give to last minute lobbying.

Such a statement as this, which is known to be the truth as far as Massachusetts is concerned, might with few exceptions be applied with equal force to the condition of affairs in almost every other state of this country. From 1907 to 1920, as secretary of a state commission which was in charge of the Massachusetts sanatoriums for consumptives and of the tuberculosis campaign in this state in general, it was part of my duties to attend hearings not only in regard to tuberculosis and matters directly related to my Board of Trustees, but also those concerning health matters in general. What has been accomplished at such hearings during these years by the various committees on legislation representing the Massachusetts Medical Society bears a striking resemblance to what has been accomplished this year, as described in the editorial quoted above. Anti-vaccination bills have been successfully opposed and killed each year, though with difficulty; many good measures have been supported and occasionally their passage secured; bad bills have been opposed and occasionally their enactment prevented. Yet as a whole it is undoubtedly true that the influence of the medical profession in this state as represented by the Massachusetts Medical Society on its legislative body, the Senate and House, is conspicuous by its absence.

Others Do Not Lack Influence

Other organizations representing various groups of men, industries, trades and occupations are not without influence at the State House. It is an undoubted fact that a union such as that of the brick layers or that of the amalgamated cigar makers can exert a powerful influence on those who represent them; any large public service corporation seems to be able to make its wants known quite definitely and clearly on Beacon Hill. In the *Boston Evening Transcript* of May 22, 1920, interesting comment is made on the influence of the now powerful Farmers' party in Ontario, Can. On two recent occasions when the representatives of the farmers in the legislature seemed about to take a certain action that did not meet with the approval of those they represented, "the executives of the Farmers' Organization issued a broadside to the farmers' clubs throughout the country, with the result that the members of the House were deluged with such a floor of telegrams and letters that they immediately reconsidered their former decision."

I do not for a moment criticize these various committees and the men serving on them who have represented the Massachusetts Medical Society and other medical organizations in this state. These men have given freely of their time and energy and have worked long and faithfully to bring about what they knew and what we all knew was for the good of the community; yet the fact remains that they have failed in the vast majority of instances to produce results. Why have they failed? The answer to this question is one that vitally concerns every physician in the country. Why does a group of men, each of whom has spent the best years of his life in training for the noblest and best of all professions, have so little influence in the community? Surely our aims and ideals are of the best. This no one can deny. Then it must be our means and methods that are at fault. No other conclusion is possible.

With this idea firmly fixed in my mind, I wrote a personal letter to the secretary of every state medical society in the country, describing what I believed to be a most unsatisfactory state of affairs in Massachusetts and asking for details as to how each respective medical society attempted to solve this problem, and the results obtained. The answers were interesting in the extreme. A summary and brief synopsis of these letters is here given.

There were thirty-two answers to the forty-eight letters I sent out. In seventeen instances, over 50 per cent, the reply was to the effect that the medical society had a committee on state and national legislation with equivalent which accomplished little or nothing. Excerpts from some of these letters show the general trend of answers and, likewise, a marked similarity:

Arizona.—"This Association has a legislative committee which takes whatever action may seem proper. Its real value is distinctly limited."

California.—"As far as I can make out, the California State Medical Society has nothing to do with legislative matters."

Connecticut.—"There is a legislative committee which appears in opposition to anti-vaccination bills. It rarely accomplishes anything. They have no satisfactory system."

Delaware.—"There is a committee on public policy and legislation. It has no influence on legislation."

Iowa.—"There is a legislative committee of five members. The amount accomplished is largely due to the per-

*Published in October issue of the Boston Medical & Surgical Journal. Simultaneous use authorized.

sonal efforts of the chairman of this committee. There is no organization in the Society."

Kansas.—"The influence of the state Society with the state legislature is not of great importance. There is a committee on legislation, which accomplishes little or nothing."

Maine.—"There is a legislative committee which appears at hearings and which has little or no influence. The greatest help comes from physicians who are members of the legislature. The medical profession at large has little or no influence."

Minnesota.—"The Association has a legislative committee, which is somewhat inactive."

Nebraska.—"There is a committee on public policy and legislation, which accomplishes nothing." The writer of this letter does not believe that anything can be accomplished by legislative committees or by direct influence.

New Hampshire.—"The Society has a legislative committee which appears before the House and Senate Committees on various bills." So far, the writer of this letter believes, this committee has been a failure.

New Jersey.—"There is a legislative committee, which has no influence. The only influence that the medical profession has is through its members who are the family physicians of the legislators."

New Mexico.—"There is a legislative committee, which accomplishes nothing."

Porto Rico.—"The Medical Society of Porto Rico has a legislative committee, but so far it has not accomplished anything favorable for the medical profession."

Suspect the Paid Lobbyist

Wisconsin.—"There is a legislative committee, which does nothing. They have at times maintained a paid lobbyist, which accomplished nothing. A committee before the legislature seems invariably to arouse suspicion."

North Dakota.—"The legislative committee plan is a failure."

South Carolina.—"Legislative committees amount to little or nothing."

West Virginia.—"There is a committee on public policy and legislation," which, in the writer's opinion, has been a failure. "Things are put off until there is due need of action, and then it is too late to do anything."

That the situation is not quite so bad as the preceding replies would indicate is shown by the following extracts from my replies from other states and comments on them:

Idaho.—My correspondent believes that the only successful plan is for the Society to put a competent paid man on the job, with instructions to get results. No details as to how he is to do this are given.

Illinois.—The principles under which the Illinois Society acts are: (1) A good, live man at the head of the legislative committee, who lives at the capitol. (2) Organization of medical men throughout the state, so that they can see their representatives in the legislature while they are at home on week ends. (3) Information given to the medical men in each county throughout the state pertaining to bills that are introduced. (4) Sufficient funds: In Illinois members of the state society are assessed fifty cents each for this purpose. (5) The emphasizing of the fact that there is no personal or selfish purpose in the arguments brought forward; that it is simply a question of keeping up the standard of health and medical legislation as it should be. Further details are given.

Louisiana.—There is a committee on public policy and legislation composed of the most influential physicians in the state. All matters are referred to this Committee. The members visit the capitol, if necessary, and use whatever influence they can, either for or against legislative matters. Its work seems to be fairly satisfactory.

Maryland.—There is a legislative committee appointed each year to take charge of medical legislation, but this method has not proved to be very effective. This year the plan is to organize the physicians throughout the state into committees which will work with the candidates for election immediately after the primaries. Their idea is to have the candidates informed regarding the type of legislation they need, even before their election.

Missouri.—The secretary of the Association is likewise secretary of the Committee of Health and Public Instruction. He keeps informed concerning all details that touch the medical profession or public health. When necessary, he sends information concerning such bills to each of the component societies in the state Association, comprising 109 county societies out of 115 counties, giving the title and number of the bill, and what it is about. The physicians then act individually as well as through the county societies. They get the names of the family physicians of each member of the legislature. The leading members of the profession then get together with the leading members of the legislature or with the governor. Special influence is brought to bear upon the Committee before a bill is given a public hearing. This, of course, requires time, numerous visits to the capitol, and frequent consultations with local physicians and friendly politicians. It is not considered wise to have a paid lobbyist. There is evidently an active and influential medical association in this state.

Montana.—"The handling of legislative problems is easy if done systematically. Medical men best acquainted with important members of the legislature talk over the desired measures and educate them on the subject." Here, again, no details are given. The plan sounds far simpler than it must really be.

New York.—The State Medical Society has a legislative committee, which for many years has been very efficient. It does not limit itself to attending hearings, but acts by personal interviews with the legislators. The New York County Medical Society also has a legislative committee, acting in unison with the state society. For several years the president of the state society has taken an active hand in legislative work. New York has adopted the principle of personal interviews and influence with the legislature. They also ascertain who is the family or personal physician of each legislator.

North Carolina.—The Committee selects one doctor in each county who can be called upon to confer with, write, or wire his representative or senator in the general assembly. There are one hundred counties, and the Association has been able to turn in a telegram to the senators and representatives in the general assembly for more than 75 per cent of these counties on a given morning. This has been of distinct influence. This plan, which corresponds closely to that referred to above of the Farmers' Association in Ontario, has many advantages.

Ohio.—A wide awake state medical society, an enterprising medical journal, cooperation of the various welfare and health agencies, have accomplished a great deal in this state. The various members of the Society, at home in conference with their legislators, have accomplished much. There is a representative from each county medical society, and these representatives get together and discuss pending legislation. The results are good.

Pennsylvania.—The president of the Society has a desk in the Department of Public Health at the state house. He is in harmony with this department. He is closely

affiliated with the medical members of the House and Senate, and attends committee meetings, not as a lobbyist, but simply as an advisor. He lets it be understood that he represents 11,500 physicians in Pennsylvania. The results depend largely upon the personality of the president of the Society. Pennsylvania is to be congratulated in having as the president of its state medical society a man who can devote so much time and who is able to exert so much influence as is apparently the case here.

South Carolina.—The president of the state medical society calls a meeting of one or more influential physicians from each county in the state during the early days of the legislature. These men go immediately to their representatives, tell them what legislation is desired, and what is undesirable. There is no expense attached to this plan.

Tennessee.—When the medical association wishes the enactment of any law in which physicians are interested, they appoint a committee which will give the necessary time and energy to complete the matter. This correspondent is opposed to the medical profession interfering in legislation, as the responsibility does not belong to them. The responsibility should be put on the legislators. The medical profession should see to it that the legislators are informed regarding what is good or bad legislation, and then leave the rest to the lawmakers. Here, again, is outlined a plan that sounds simple enough but is not easy to carry out.

Politicians Respect Organization

Texas.—There is a legislative committee, consisting of the secretary, president, and three others. The secretary of the Association is secretary of this committee, or Council. He keeps the Council informed and active in regard to legislative matters, and on him depends the success of this plan. The society employs a man who remains constantly with the legislature and keeps the secretary thoroughly informed as to the legislative situation as it pertains to public health and the medical profession. Telegrams, letters, and other methods of appeal are used, all having been carefully prepared in advance. Educational propaganda is carefully conducted with the various county societies and their legislative representatives. It is necessary to impress legislators with the fact that the effort being made is organized, and that a record is kept of the proceedings. Those who expect to remain in politics have a wonderful respect for organization.

Washington.—There is a legislative committee, but it has been hampered in its work by the lack of a constructive program. They have come to the following conclusions: (1) The best time to interview a legislator is prior to his election. (2) A constructive program must be adopted and must be patiently followed from year to year. (3) This program must be for the best interests of the public. (4) The legislative committee should have complete freedom of action. Individual action should be discouraged.

West Virginia.—As mentioned above, there is a committee on public policy and legislation which, in our correspondent's opinion, has been a failure. Things are put off until there is dire need of action, and then it is too late to do anything. A legislative committee should go to work on the legislators before their election, if possible, by personal interviews. It is important to know the family physician of every legislator.

Here, then, is the evidence which, as everyone will admit, goes to show fairly clearly that the medical profession in this country as far as the individual states are concerned and indeed, in my opinion, as far as the country as a whole is concerned, is not the power for good that it should be. Can anything be done to improve this state of affairs? This question I would strongly answer in the affirmative, and would make the following suggestions:

Medical Profession Lacks Drive

(1) Education of the public as to its needs in health matters and legislation therefor. This should be done by articles of local interest whenever possible, printed in *newspaper English* in the daily and weekly lay press. Provided such articles contain news and are of local interest, every newspaper will be glad to print them and will recognize their importance and value.

(2) Education of the legislators. This is a difficult task. Find out the family physician of every legislator; instruct such physicians as to what is needed and obtain their cooperation and promise to interview the legislators in question personally in regard to important subjects. Find out the views of each legislator prior to his election and make such views favorably or unfavorably known to the physicians and the electors of his district.

(3) Education of the medical profession. In the medical press and by personal letters and at medical meetings impress upon every doctor that it is part of his duties and part of his responsibility to the public to educate his patients and the families under his care concerning public health matters and preventive medicine.

(4) Every state medical society might well employ a capable man at full or part time to assist in the details necessary to carry on the campaign outlined. He should also prepare the means and methods so that at short notice a given legislator or group of legislators can be deluged with letters, telegrams, and personal interviews urging his action for or against certain measures. The average legislator will not be greatly influenced by a legislative committee representing what is to him a somewhat vague and intangible thing such as a state medical society, particularly when he hears from such a committee at a time when his mind is usually already made up as to which way he intends to vote. He will be influenced, however, by appeals from men, constituents of his, whom he knows personally, from his own district, and who he likewise knows have large influence among the voters of his district. Such influence will be all the greater if it is brought to bear at an early stage, when his opinion is still in the formative state.

These are, of course, merely suggestions, the details of which must depend upon local conditions. I believe, however, that by carrying them out in whole or in part the medical profession will be a greater power for public good than it now is.

FOR UNITY IN SOCIAL WORK

The need of greater unity in social work was considered at a conference recently of officers of various organizations engaged in such work, among whom were Secretary of War Baker, Charles D. Orth, president of the National Security League, and Dr. George E. Vincent, president of the Rockefeller Foundation.

Mr. Orth announced the appointment of a committee of the National Security League, headed by David Jayne Hill, to prosecute the work of the coordination and amalgamation of patriotic and civic societies throughout the country. Every field of social service is overdivided, declared Secretary Baker, who proposed that the various organizations establish a central agency to survey the field of social work with the view of merging similar societies. Such action is in the interest of efficiency.

THE PSYCHO-EDUCATIONAL CLINIC—ITS CONSTRUCTIVE POLICY

By HERMIONE L. DEALEY, Psycho-Educational Clinic, University of Minnesota, Minneapolis, Minn.

If, speaking in in terms of its recent work, the Psychological Clinic in six months handles one hundred cases, and as a result can offer constructive suggestions which make for needed adjustments, how great must be the actual need of systematic assistance for all school children!

Without a realization of the needs of the child in terms of its mental and physical health the power of the school as a socializing agent must remain purely nominal. Owing to general ignorance of individual capacities, misfits keep piling up, withdrawals multiply, and there results a constant increase in the case records of social agencies. The Clinic is an effective social aid in the promotion of better health through the creation of better educational adjustment.

TODAY certain methods are characterized as "modern;" for instance, methods of modern warfare, methods of combating different diseases, and to some extent methods employed in education. The term "modern" is considered significant because it suggests the application of scientific knowledge and implies that genuine social progress is dependent upon adequate diagnosis followed by constructive measures. Among different agencies employing such modern methods as means of best approach towards the social goal is the psycho-educational clinic.

The Psycho-Educational Clinic is a laboratory wherein are carried on intensive psychological measurements of individuals, the results of these measurements forming the basis for necessary educational adjustments. In the phrase "educational adjustments," the word educational is to be interpreted broadly, that is, not only in its application to the school room situation but also with reference to situations experienced every day. Methods of the Clinic are "modern" in that through scientific measurements capacities are noted, defects are ascertained, and causes for poor habit formation are brought to light. On the basis of these data it is possible to offer constructive suggestions as to what may well be done to develop capacities, to remedy defects where this is possible, to reform bad and to establish good habits.

In so far as the work of the Psycho-Educational Clinic is educational in nature the question may be raised, does not the clinic assume duties inherent in the democratic nature of the American school system? Yes, certainly. But what the clinic *is accomplishing* on a small scale, American schools are still *going to do* in years to come. There is a vast difference between the two conditions.

For three important reasons schools are not yet prepared to meet certain fundamental obligations. In the first place, the social mind has not yet sufficiently grasped the importance of early and systematic analysis of the intelligence and mental characteristics of school children so that method of teaching and content taught may in truth be related to the "nature and needs of the child." In the second place, school administrators and teachers are not trained to understand educational requirements in terms of mental and physical developments. In the third place, changes evolve slowly. The process of "psychologizing" education is confronted by a social bulwark of old behaviour patterns which must be broken down and replaced by those of the new scientific era.

Causes for this deficit in American education are found in the almost invariable grouping of school children according to chronological age. As a result, by natural process the big amount of retardation and the little amount of acceleration and all the numerous concomitant conditions pile up. Then the public finds itself confronted with "educational problems." From the psychological point of view facts show that each child develops according to his capacity, not according to his chronological age, and that the quality of school achievement is directly correlated with natural intelligence and environmental influences. The American "freedom" and "equality" must be interpreted in terms of the child's capacity to react to opportunities offered; otherwise our educational democracy is impractical. As long as educators are ignorant of the intelligence of children, they can not know what educational opportunities to offer. Hence, while energetic psychological research is being carried on in order to obtain facts wherewith to create a favorable public attitude towards the validity of applying modern methods to education, the psycho-educational clinic, not waiting for the entire school system, seeks to hasten matters by showing what can be done.

Organized for Present Needs

This article, although it may describe in general the nature of the psycho-educational clinic as it exists in different states, refers specifically to the Clinic organized in the fall of 1916 in the College of Education of the University of Minnesota and conducted in cooperation with several clinics in the School of Medicine. Advantages of this alliance with the School of Medicine are obvious. Facts of physiological health must be known and may best be obtained from medical authorities, for instance, those in the Pediatrics Clinic, in the Clinic for Nervous and Mental Diseases, in the Ear and Eye Clinic. Furthermore, a comprehensive understanding of individual cases requires a *social history*. This is in part obtained through cooperation with the Department of Social Service of the University Hospital. A special outline indicating information desired by the clinic is followed by the departmental social workers. Additional facts, with especial reference to school progress, are obtained by members of the clinic or are submitted by those social agencies referring cases. These data—mental, physical, and social—are placed on record and form the basis for diagnosis, recommendation, and follow-up.

Individuals are referred to the Psycho-Educational Clinic by the State Board of Control, the Hennepin County Child Welfare Board, the Women's Cooperative Alliance, the University Hospital, the Visiting Nurses Association, orphan asylums, maternity homes, clinics of the University medical school, public and private schools, private physicians, and parents. The great variety of agencies cooperating with the Clinic suggests the range and depth of the problems involved: for instance, the superior child, the delinquent, the backward child, the

borderline case, the type which "cannot hold a job," the child who is handicapped by poor habit formation, the feeble-minded, the child held for adoption. Any person through regular or special appointment may be examined at the Clinic. No fees are required. All individuals, unless ignorant of the English language, are tested by the Stanford revision of the Binet-Simon tests; results so obtained are often supplemented by a partial or complete mental rating based on performance tests.

In order to indicate more definitely the attitude of the Psycho-Educational Clinic toward mental health typical instances will be given where there is obvious need for constructive educational adjustment.

Problem of the Superior Child

(1) Psychological tests do select the "superior child." From recent examination the Clinic has placed in special file the records of ten children each with an intelligence quotient of 120 or above. Chronological ages of these children range from seven years seven months to fourteen years and eleven months; but the mental ages are from ten years nine months to eighteen years one and one-half months. Intelligence quotients for the group range from 122 to 180. Despite the great discrepancies between chronological and mental ages, only two children were two years advanced in school work, six were one year advanced, and two were not advanced at all. The big cause for redajustment in cases of this nature is the *lack of opportunity to develop according to capacity.* The mother complains that her child "does not seem to be doing as well as he should." The teacher admits the child seems bright enough, nevertheless he lacks "attention," indulges in "day-dreaming," and ignores school "discipline" in general. Parents and teachers feel the need for readjustment, but are at a loss just how to bring it about.

These children have a right, if there is freedom and equality in education, to demand sufficient incentives and sufficient depth and breadth in school work to keep them constructively busy and happy. This means the broadening of the regular course of study or rapid promotion through regular school work or the insertion of special classes fitted to meet requirements of the superior group. In emphasizing this aspect of psycho-educational analysis the Clinic stands as an enthusiastic advocate for the utilization of the most valuable mental capacities of individuals.

The Other Extreme

(2) Reverting from the superior child to the extreme of feeble-mindedness, new problems arise. A girl aged twenty years, is referred to the Clinic. She has a mental age of nine years, an intelligence quotient of fifty-six and is classified as a low grade moron. Her father and mother separated several years ago; the only other child died of "heart failure." The girl attended school until seventeen years of age, first competing in the regular grades, but finally finishing in a special class where she was doing something like fifth grade work. Since leaving school she has stayed at home, without friends, with no definite training for anything, helping a trifle around the house,—enjoying (presumably) "life, liberty, and the pursuit of happiness." Of what earthly use has the general education of the four grades been to this girl? How many periods of depression has she experienced owing to lack of capacity to compete with other members of the class and to the teachers' attitude towards her inability to learn! The Clinic sees that the girl has been allowed to cope with experiences obviously unsuited to her nature; she has been encouraged to enlist much attention and time from teachers without being able to give the desired response. This illustrates a big waste of time and energy and the suppression of happiness.

A mother, about thirty years of age, is found to have a mental age of eight years and an intelligence quotient of fifty. Her two children, twins, are both high grade morons. The mother is immoral, her husband is "bad," the home and neighborhood are very inferior. This family makes no contribution to society; it should never have come into existence; it might have been avoided through an early knowledge of the girl based on psychological measurements.

A child of eight years and two months scores a mental age of three years ten and one-half months and an intelligence quotient of forty-seven. He has distinguished himself by repeating the C division of the first grade for the fourth time. The teacher rather despairs that he can learn. The parents think the child just a little different from other children, yet believe that he will make good in time. The Clinic, on the other hand, notes the intelligence quotient, a history of disease, and the frequent occurence of convulsions.

A girl over twenty years of age of cheerful disposition and "pleasing personality" attempts high school work but fails. The Clinic discovers a mental age of nine years nine months. Evidently personality is a factor in determining a child's progress through the grades. Psychological measurements discount this factor and account for the failure in high school.

Significance of the Work

In short, during the past six months thirty feeble-minded individuals and thirteen borderline cases have been brought to the Clinic. These cases illustrate specifically the fact that neglect to employ early psychological diagnosis results in a maximum of waste, a minimum amount of learning, and an increase in the number of social dependents. Moreover, as the chronological ages of these individuals increase, degenerate offspring are apt to materialize, either with or without marriage. Individuals of this type who eventually are to be segregated should receive early attention in order to conserve the country's time, energy, and financial resources. Surely such cases need not be multiplied to show the significance of the clinical work. The Clinic seeks social improvement through timely appreciation of individual deficiencies and through isolation of those who are certain to retard social progress.

(3) The Clinic faces the problem not only of effecting adjustments for superior and for feeble-minded individuals, but also of analyzing home and school conditions in terms of habit formation and of emotional reactions. Certain persons, though of normal intelligence, do not seem able to "get along." The child of normal intelligence who has no brothers and sisters and who has been kept by himself in adult atmosphere, when sent to school does not know how to play with other children since he has never formed habits of group play: he is averse to following directions from the teacher because he is accustomed to *reason* wtih his parents, not as a child but as an equal. Hence in the eyes of the school he is malicious, unmanageable, and a big "school problem." The boy who has been isolated in the country and has never attended school, on coming to the city school is able to talk only in rare monosyllables and finds it impossible to read before his class. The new situation arouses fear, which acts against adjustment. One child who is obviously backward in school and of low normal intelligence is found to come from a home full of sickness and depression.

Though less than twelve years of age, she assumes the responsibilities of an adult; and is rapidly forgetting how to smile.

Maintenance of mental health is ever dependent upon the continuous process of proper habit formation in terms of necessary environmental adjustments. When these adjustments can not be met, conflicts arise and there is need for a scientific study of causes and effects in order to remedy the situation.

Deserve Chance to Develop

(4) Children who are mentally retarded have an especially hard time getting an opportunity to develop. A small boy of six years six months was brought to the Clinic with the suggestion that he was probably feeble-minded. Test results showed retardation of a little over a year, an intelligence quotient of eighty. Inquiry disclosed the information that the mother had died when the boy was a few months old and that he had been sent to live with his grandmother. At four years he was characterized as stupid, unable to talk, and apparently devoid of intelligence. The father remarried and the stepmother rather objected to the child's return to the home. Now, encouraged by the fact that the boy is not feeble-minded and after observing his progress during a period of attention and training, the woman expresses her willingness to keep him. In school, however, the child is not able to do the work of the first grade. According to his mental age he should be in the kindergarten instead of attempting the work of the first grade and having to experience failures. Evidently an appreciation of the way in which children have been allowed to develop and a knowledge of the amount of mental retardation can help eliminate a lot of trial and failure in home and school education.

The illustrations cited under the four headings above are naturally brief and rather generalized, yet they may serve to indicate the great need for educational adjustments based on psychological measurements and their interpretation in terms of all available information. If speaking as before in terms of its recent work, the Psycho-Educational Clinic in six months handles about one hundred cases, twenty-one of which are classified as "superior," sixteen as mentally backward, eighteen of average intelligence, thirteen as borderline cases, and thirty-one as feeble-minded, and as a result can offer constructive suggestions which make for needed adjustments, how great must be the actual need of systematic assistance for the thousands of school children!

The American school is recognized as the Nation's big and universal socializing agent. It has the power to observe and to control human behavior over an appreciable period of time. Yet, without realization of the needs of the child in terms of its mental and physical health, this power must remain purely nominal. In which case there will continue to be a general ignorance of individual capacities, the number of "misfits" will keep piling up, withdrawals will multiply, only a small percentage of children will get the "common education," and there will be constant increase in the case records of social agencies. In competition with this situation the Clinic asserts itself as the small but virile forerunner of activities which in coming years will be practised throughout the entire American school system.

Students enlisted in the work of the Psycho-Educational Clinic at the University of Minnesota not only observe the different cases directly and get a real comprehension of the human problems involved, but also learn much through their own work in different schools. Within the year tests have been made in eight different schools. Seven students, working systematically for two academic quarters, have given a total of one hundred tests in three of the schools. Results obtained are unquestionably valuable from the point of view of the students themselves, of the teachers, and of principals.

Finally, as an agent active in modern forms of social service the Psycho-Educational Clinic makes special effort to enlist the intelligent interest and cooperation of parents, of social workers and of nurses in public health service. To this end special demonstrations of methods and results are given, but more often results of the clinical work are explained through lectures. Almost without exception social response has been enthusiastic and genuine. Hence, when each year there is a significant increase in social appreciation of this kind of work, it may well be said that the Psycho-Educational Clinic both in policy and in practice is a "modern" agent for the promotion of mental health through the creation of better education adjustments.

THE STAMP OF HEALTH

The penny tuberculosis Christmas Seals are the greatest factor in financing tuberculosis work. In addition to the seals, the Association is offering "health bonds," guaranteed to bring in extraordinary returns in individual and community health.

Tuberculosis is no respecter of persons. Education of every class of the country's population on preventive measures is the only safeguard. Christmas seals have made possible the furnishing of milk to the children in the open air schools and have financed tuberculosis clinics; infant welfare clinics; health crusade work among the

school children, an educational exhibit that has been viewed by more than a half million persons in Chicago and Cook County; an automobile "traveling clinic" which has been responsible for the establishment of a number of permanent clinics; public nursing work and a vast amount of propaganda.

The actual work done by the local anti-tuberculosis societies is necessarily limited by the amount of funds at their disposal, and if the field is to be covered properly, each and every one must buy his quota of Christmas Seals.

WORLD-WIDE FIGHT ON TUBERCULOSIS

The National Anti-Tuberculosis Commission, under the presidency of Leon Bourgeois, has sent out invitations to similar committees in the United States and the countries adhering to the League of Nations to send delegates to Paris for the purpose of creating an international organization to fight tuberculosis.

THE HEALTH CLASS IDEA

By IRA S. WILE, M.D., New York City

At last in medical service the emphasis is placed where it belongs—on health and on that harmony of mental and physical factors necessary for the complete functioning of the human organism.

The achievement of this objective will promote a better understanding of childhood in all directions and will involve the intelligent cooperation of relief, medical, social, psychological, and educational as well as in all other related fields.

What is perhaps more important for its ultimate success is that measures are included to arouse the interest of those it purposes to help. The program for child welfare thus extends to the family. Such coordination of effort tends to cover the whole field and spells a state of Public Health.

AMONG the numerous efforts at hospital and dispensary developments, none is more instructive than that to promote the organization of enlarged pediatric services. Various schemes have been proposed, involving an interlocking of the hospital and dispensary services with the multiple divisions of the dispensary clinics. Special classes have been organized on the basis of chronology, pathology, or social adjustment. There has been a tremendous impetus to increase the social value of hospitals and dispensaries through the establishment of the humanized outlook upon the problems of infancy and childhood. The exceedingly important part that ignorance and poverty play in the causation, maintenance, and variation of handicaps, defects, and diseases of childhood is well known, though by no means as widely acknowledged as the truth warrants.

Emphasis on Incipient Disease

Modern medicine is constituted for many by the dramatic preventive aspects whose primary significance is illustrated through such accomplishments as the building of the Panama Canal, the reduction of the mortality of tuberculosis, the campaign against the control of venereal diseases, typhoid fever among armies, the conquest of malarial diseases, and the sanitary and hygienic control of infantile diseases. Socially, the main influence in preventive medicine is found in the instrumentalities that work through families or through the community. Prenatal clinics, infant welfare stations, and clinics for children of pre-school age exert their maximum benefits by direct influence upon the parents, particularly the mothers, and serve to raise the standard of the home environment, even though the means employed are purely educational. When one approaches the work of the medical inspectors of schools and school nurses, it is appreciated that the main efforts are along the lines of detecting incipient diseases and handicaps or defects, prompt attention to which improves the physical well being of individual children.

Communal efforts at raising familial standards are found in enactments relating to housing regulations concerning garbage and sewage disposal, the protection of water and food supplies, and similar well known santary rulings. Of equal value are such efforts as are made to secure legislation dealing with accidents and diseases, establishing minimum wage laws, advocating shorter hours of labor, and establishing control over hazardous industries.

Thus far hospitals and dispensaries have been regarded, for the most part, as agencies mainly concerned in the treatment of diseased individuals. In some few instances this concept has been expanded to include the maximum physical rehabilitation of the patient, by means of physiotherapy, occupational therapy, and vocational re-adjustment. As a whole, our hospital and dispensary system has been backward in recognizing the advances in prophylactic medicine, and in expanding or readjusting their organization so as to apply the principles of preventive medicine in their current relations with patients.

In a sense, curative medicine and preventive medicine are not antagonistic in purpose, but both aim to advance public health. The cure of diphtheria, typhoid fever, and tuberculosis by the elimination of foci of infection presents a definite prophylactic phase. The prevention of diphtheria and typhoid fever, however, is far more useful to the community, is more economically accomplished, and results in a more adequate protection for the community than is secured through a delay of the protective machinery until after such diseases already exist. It is for this reason that one notes with especial interest every attempt to readjust hospital and dispensary methods to the point of view of preventive medicine. After all, the essential and motivating factor is the point of view that recognizes the possibility of enhancing public welfare through inhibiting disease factors; that appreciates familial health as the foundation of public health; that realizes the worth of educational and social agencies in the safeguarding of individual, familial, and communal welfare.

A New Departure at Mount Sinai

A little over a year ago at the Mount Sinai Hospital dispensary there was laid the foundation of a dispensary plan for creating a department of preventive medicine. The point of departure was found in the establishment of a class whose original aim was to help children of the pre-school age. This was selected in view of the fact that medical inspection of schools had revealed a large percentage of children suffering from a great variety of defects and handicaps, most of which might have been obviated by attention during the pre-school age, while others might have been eliminated previous to entrance upon school. It appeared desirable to attend to the physical welfare of the children before the beginning of their school career in order that they might be properly prepared for undergoing the educational processes. It appeared rational to put them in fit condition, thus making them potentially most capable of receiving what is termed an education. It required but a few sessions of the class for pre-school age children to make manifest the folly of limiting the service to the children of the pre-school age group. Few of the children were without brothers and sisters, and the interrelations of family life made it necessary to attack the problems of each child on a familial basis. As a result, the Health Class for children widened its conception of its duties and responsibilities, and aimed to function in the larger sphere of familial health.

More than a year has passed, and I am therefore able to pass judgment upon my efforts and to evaluate the

results of the class management. More than four hundred children have been under care, about 50 per cent of whom were of the pre-school age. More than half of the children had previously been under the care of a private or clinic physician. A large proportion of the youngsters were not believed to be other than healthy. From the beginning, I have held to the idea that a child is more than an anatomic system, offers more problems than those classified as nutritional, respiratory, cardiovascular, or nervous. Each youngster is an organism for whose complete functioning there must be a harmony of physical and mental factors, functioning adequately and without maladjustment in its own particular environment. For this reason, I selected the term "Health Class" as indicating my interest in the general health of children. It is impossible to begin prophylactic work with children without concern for their nutrition, but inasmuch as nutrition itself is dependent upon various other factors, it is patent that the term nutritional class does not satisfactorily describe its purpose. While some children give evidence of cardiac impairment, many of these disorders are functional; they respond to improved nourishment, and it would be far-fetched to call the class a cardiac clinic. Many children are mentally retarded; they possess low intelligence quotients, and although they are given the advice and treatment indicated for their improvement, I do not deem it wise to call the class one for mental hygiene. A number of children present serious problems of conduct and behavior, but it would be inaccurate to refer to the class as one devoted to the psychological problems of childhood. As a matter of fact, the whole health of the child is the subject for consideration, whether it involves the physical, mental, or moral phases.

At the present time, it would be possible to describe my efforts as leading to a more thorough understanding of childhood in all directions, involving cooperation with every available agency interested in, and valuable for, promoting child welfare. These include relief, medical, social, psychological, and educational groups. In the beginning the children were referred to the Health Class from the Social Service Department of Mount Sinai Hospital. After a short time the individual members of the class were responsible for rapidly increasing the membership. Later on, children were referred from various special clinics, many by the visiting nurses, the Department of Education, charitable organizations, public school visiting teachers, infant welfare stations, private physicians, and individuals generally interested in preventive medicine.

The Case of Jane Doe

To understand the workings of the class, it might be well to follow a typical child through its machinery. Little Jane Doe arrives with her mother and enters the reception room, upon the walls of which are pictures, posters, and a variety of educational material. While awaiting her turn, the youngster is permitted to play with toys that are available, read a book, draw on the blackboard, talk to other children and otherwise conduct herself in a normal child-like manner. The mother may be interested in one or more of the wall charts, or may possibly examine an exhibit of the proper shoes for children, an exhibit of a child's breakfast, or other material designed to catch her attention and stimulate her enthusiasm for the health lessons she is to receive.

In turn, Jane Doe and mother are taken by the social service nurse to a desk where a general history is taken by a volunteer aid, after which the child is weighed and measured, the shoes and heavy clothing being removed. She is then permitted the utmost freedom until her time for medical examination arrives, when a physician examines the child, who is stripped, and makes a complete record of her physical condition. Let us assume that Jane was slightly below weight for her age and height, had very much enlarged tonsils and adenoids, several carious teeth, pediculosis capitis, and a pronated foot. This is not an unusual picture and will serve to indicate some further procedures. The doctor has ascertained the hours of rising and retiring, the type of dietary employed in the home, the use of stimulants, and such other factors as are pertinent. After completing his examination he discusses Jane with her mother, pointing out the various defects noted, suggesting the type of dietary that is to be employed and the necessity of giving careful attention to the various defects that are present. There is reassurance as to the ultimate outcome for the child and the advantage of following advice is emphasized. A note is made on the history blank that the social visitor, who also is a nurse, when going to the home, shall give such instruction as is required in the particular home that will lead to the elimination of pediculosis capitis, and will inform the mother how to make the requisite budgetary adjustment to enable Jane to receive the milk, cereals, and green vegetables that she requires, instituting a requirement which will obviously benefit the rest of the children constituting the new generation in the household. Jane is referred to the dentist, the Nose and Throat Department, and the Orthopedic Department. The social worker makes the appointments for each of these visitations in order of necessity, and informs Mrs. Doe that she will soon call upon her. Thus ends the first day at the class, with the giving of a card of admission to the mother. I may say at this time that there is no fee for the service thus given.

The social visitor visits the home during the week, imparts the information as directed, and makes the necessary social investigation. It is found, let us assume, that Mrs. Doe earns seventeen dollars a week, and lives as a widow with three children in three rooms, for which she pays twenty dollars a month. It is ascertained that a charitable institution is interested in her, that she is willing to cooperate, but has become somewhat discouraged. Jane has been in school one year, and was left back one term. Jane is the oldest of the three children. Before the next visit to the class the Nose and Throat Department has seen Jane and reports that the tonsils must be removed, thus corroborating the original judgment of the examiner. The orthopedist states that the inner soles should have a quarter of an inch lift to aid in correcting the beginning deformity. The reports from the special clinics are noted on the history cards. Corrective exercises are prescribed for faulty posture and the child is taught the correct position of standing and advised to practice her exercises daily, before a mirror if possible. On the second visit one week later, Jane is found to have gained one-fourth of a pound; her hair has been cleaned with larkspur, and an effort has been made to free the head from nits. She reports that she has been drinking two glasses of milk a day, and has stopped all her coffee. She now goes to bed at eight o'clock instead of nine. Mother and child are complimented, and the child is given a little book to take home because she seemed interested in it and not because she asked for it. The following week she returns after having had a first visit to the dentist, which is the beginning of the corrective dentistry that is necessary. The social visitor gives her a tooth brush, and the doctor urges her

to make use of it. She has gained again, and is ready to follow out the dietetic injunctions with regularity.

During the course of the next few weeks her tonsils and adenoids are removed following which there is the customary loss in weight, and after that she rapidly improves in nutrition, until at the end of six months she has completely made up her deficiency and possesses an improved vitality, greater interest in her own welfare, and the family is cooperating as a whole for the improvement of personal health. I may say, also, that by this time Jane's brothers and sisters have been enrolled as members of the class, and have undergone similar examinations with follow-up work leading to the necessary corrections. Ordinarily, Jane would have been classified as being fit for a nutritional class. In view of all that was done for her, one would not be justified in regarding her state as merely impaired nutrition. A modification of dietary would have been insufficient. It is true that her nutrition improved with every new adjustment of her physical structure, but her health as a whole was under consideration.

The Health Class a Clearing House

The Health Class has thus served as a clearing house for other clinical departments, but the essential point of departure lies in the fact that the children are merely referred to other branches of the dispensary for specific service and immediately return to the Health Class for continued oversight, direction, and guidance. All elements entering into the welfare of the child are secured through the medium of the Health Class, and the interpretation of all results of counsel comes from the examiners of the Health Class. Under this plan children are not divided up into pathological sections, or stigmatized by being placed in one particular group with which they must continually report, as if their whole lives had to be centered about one particular portion of their anatomy or their destinies were to be determined by one phase of maladjustment.

While I have given a type illustration, I may say that the average number of physical defects per child has been found to be three; the combination, however, varying greatly, particularly among those possessing five to eight defects each.

New Impulses Arise

It is difficult to analyze the various types of children whose health has been improved, nor will a cold statistical tabulation suffice to indicate the character of work performed. From the standpoint of gain in weight and height it is possible to establish certain figures demonstrating a fact without need of proof, that normal children, properly and adequately fed, under conditions of reasonable hygiene, will exhibit normal growth, as evidenced in weight and height. For the sake of a clearer elucidation of the ideas that have been followed I shall refer to certain particular types of children to indicate the breadth of the field that is to be tilled. This becomes necessary because it is practically impossible to arrange statistically increased hope and happiness, better behavior and more cheerful home service, improved speech, motor coordination, application, concentration. One can enumerate the number of children cured of nail biting, enuresis, lisping, or the number referred to special classes, to institutions, to picnics, the circus, etc.; but these fail to tell the story of child improvement. There is no adequate numerical index of joy, social impulse, educational interest, the release from fear, or self control, though patently these enter into the health of children. Wherefore, I omit tables showing the number of defects observed and corrected, the gains in weight, the average time under direction, etc.

The B. family, consisting of four children, was referred by the orthopedic clinic because the youngest child, age twenty months, was unable to walk and the other children showed profound disturbances of a rachitic character. The rickets in these children resulted from prolonged lactation with inadequate diet. Discontinuance of the breast, and a new dietary sufficed to enable the youngster to walk within one month and he was then referred back to the orthopedic clinic for such specific care as might be required. A second child, with pronounced *genu valgum*, and tremendous bowing of the legs, after a short period of dietetic reconstruction walked more easily, and was referred for surgical correction of the deformity. The youngest child had a severe eczema and, later, a furunculosis, for which attention was given at the dermatological clinic, during which period the child continued to have the necessary corrections made for enlarged tonsils and improper feeding. The entire family received the benefit of the advice of the social worker and the physician. Family rehabilitation was a primary result of the children's problems.

Alfred D., a handsome boy of eleven, with a mental age of eight, was referred by some member of the class because his mother was complaining of his fits of temper. Investigation revealed that three younger children of normal mentality were abusing him, calling him "fool," and provoking him in other ways. These children were seen, their cooperation solicited, and the mother informed of the need for more understanding of the peculiarities of the defective child. The school was visited and arrangements made for following his work in an ungraded class. The mother was given personal advice concerning educational methods to be employed in developing her child, and was instructed regarding the advantages and methods of a concrete education in the home, and the benefits of occupational opportunities. The end result was most satisfactory. The home is now harmonized, the fits of temper having subsided, and school work has progressed most favorably. Three other children in the family have received dental correction, and training in posture. The family dietary has been revised, thumb-sucking by one youngster has been overcome, as well as enuresis. The mother has attended a dietetic class, and is anxious to cooperate in every way to maintain the family welfare upon the high plane which has been suggested for her.

Little P. R., aged six, was referred by a pediatric clinic as a probable defective. On original presentation at the class the child was a pathetic picture, unwilling to enter the room, with a countenance perfectly blank, hostile, obstinate, distinctly repressed and unhappy. He would not play with other children, moped at home, made use of no toys, and was thoroughly evidencing antisocial attitudes that were a serious handicap to the development of his personality. Physically, he was an excellent specimen, comparatively free from significant defects. Within one month, after familial training, and an effort to handle him understandingly, his true character emerged. He began to play, to smile and laugh, to talk, to read, and, having been placed in school at the suggestion of the examiner, he evidenced a capability commensurate with the estimate of his intelligence. In other words, he functioned as a normal child of six. Despite an attack of pneumonia and empyema he has continued to live and act normally, and a suspected defective is prepared to develop and live as a normal child, freed from the incubus of being misunderstood.

Fannie W., aged twelve, while originally examined as part of a family of four, all of whom were below weight, was taught to overcome her expressed dislike for the types of foods most helpful to her. She soon gained sufficient strength to make up her nutritional disability to resume a normal posture, and to fight hard for the overcoming of the persistent habit of nail biting.

A six-year-old child, said to be exceedingly vicious, was brought to the class, principally because of his addiction to cigarettes. His ambition to become a pugilist was recognized, and the fact that his cigarette smoking was merely part of a desire to imitate manliness made it possible to work with him on a sound basis, which soon resulted in freeing him from his addiction. Incidentally, his teeth received attention, and his underweight was corrected, while the family was being instructed in the

proper methods of meeting his exhibitions of irritability.

A large number of children have been educationally readjusted through the utilization of mothers, brothers, and sisters who have received personal instruction in matters of education, as well as suggestions concerning the methods of interesting children in the common branches. For example, a partially deaf child, at the age of eight, incapable of measuring up to the standards of a five-year-old child was accordingly regarded by the parents and relatives as mentally deficient. The class referred her to a school for the deaf where excellent progress is now being made. Similar adjustments have been made for the blind, or partially blind, for high grade imbeciles and morons, whose physical welfare has received constant attention while the educational work was being continued at the regular schools. The class has fostered the mental attitude and has sought to aid the moral growth of the children. Speech defects, such as lisping, stammering, lallation, and defective voice placing have received careful study and attention, and are not passed over as being unrelated to physical well being. The effects of such speech defects upon character are well known and for this reason every effort has been made to cure children suffering from these handicaps. Practically every one of the children in this category has been cured.

A number of children presenting mental defects which were suspected of having their origin in disturbances of endocrine glands, have, after reports to and from the neurological clinic, received the requisite medication indicated for their improvement. Results in this direction have not been completely satisfactory, due to the lack of complete knowledge upon this phase of work. It has been possible to begin early work with cretins, a few of which have presented themselves.

In several instances children have been referred as suffering with conditions for which surgical relief has been indicated, as the presence of hydrocephalus, and brain tumor. Two instances have been noted of fractures of the clavicle, in which treatment for rheumatism had been instituted before the children entered the class. These were promptly cared for in the surgical department.

Outside of the medicaments given to defectives, practically no drugs are employed. Food, hygiene, water, rest, family adjustments, attention to posture, and training of the bowels have sufficed as active factors in the relief of the majority of conditions which the children presented. There are no pills for constipation, no drugs for enuresis, no bromides for nervous manifestations. Even the large group of children with cardiac murmurs are given an opportunity to lose their functional disturbances under natural conditions. When indicated, electrocardiograms are taken, the x-rays are employed, and consultation with a cardiac specialist is requested. The children, however, are not referred to a cardiac class for regular attention, but always return after examination to the Health Class for continuance of the general oversight of their welfare and development.

I need not call attention to the advantage of health service of this kind. Not merely does it suffice to detect incipient chorea, beginning spinal curvature, dental decay, diseased tonsils, small hernia, early tuberculosis, and enlarged glands, but it enables the prompt institution of the special treatment for these defects. Far more important is the opportunity for examining supposedly normal and healthy children with a view to preventing the development of these numerous defects, and the purpose of raising the standard of personal efficiency. I have not dwelt upon examination of the eye, nose, and throat, because these have long been recognized as of immense importance, but I cannot avoid emphasizing the increased benefit of such examination, whenever possible, prior to entrance upon school work.

The Service Many Sided

In the accomplishment of the work thus briefly and inadequately described, there are required physicians and social workers as a nucleus. In addition thereto much is to be gained from the services of a clinical psychologist, a trained teacher of domestic science, and volunteer aids willing to take histories, entertain children, and assist generally in making and keeping appointments with different agencies to which children must go for particular services. While this personnel is requisite for the best type of health service, much can be gained by beginning the class with only doctors and social service nurses. It is essential, however, that the examiners possess some familiarity with mental hygiene, educational methods, and social agencies, even though without a sound understanding of the social approach to medical problems. It is difficult to secure doctors whose basic ideas of medicine are thoroughly adapted to the concept of preventive medicine in its social relations. This is, perhaps, the greatest obstacle that must be overcome by one desirous of establishing a health class founded on the broadest lines.

In the Health Class at Mount Sinai Hospital dispensary, I have endeavored to apply the principles of public health education in every way possible. Wherever a parent or child turns, there is material from which knowledge may be derived, either at a glance or as a result of reading for a moment or two. Exhibits, frequently changed, are carefully set up to attack various problems in dietetics and clothing. Here and there are pictures, utilized for their mere beauty, colorfulness, and attractiveness, designed principally to train the eye to seek for the various more important messages hung upon the wall.

To establish an atmosphere of friendliness, all discipline is abolished save the self-discipline of a group possessing a common interest. The weighings and measurings are not in private, but are public, so as to create a competitive spirit and a helpful interest in the welfare of others. Toys, games, books, and a blackboard are at hand for use before, during, and after the period directly devoted to the study of the children. An expert dietitian has held classes for mothers and for children with much profit and benefit. It is my intention, with the cordial assistance of the social service department of the hospital, to establish various types of classes for children in order to capitalize their interest, not merely in their own health but in the progress of the class.

It is rather astonishing to the visitor to note examinations and consultations being given in the presence of many parents and children, but without undue excitement or disturbance. This feeling of friendliness in the group is a most hopeful sign, particularly when in the group one finds brothers and sisters, mothers, fathers, and other relatives who have come to care for children and to receive the advice that is available. It is equally striking to note that some of the children would feel lost without their weekly visit.

The follow-up work is such, that practically every family is visited once a month. Nearly every child reports as frequently, though the large majority of children are so thoroughly serious in their health work that they return even though their presence is not solicited. Many of the children have reported more than forty times out of a possible fifty-two visits a year. For the first few

months weekly visits are required in order to keep close check upon the progress that is made in the improvement of the child and in carrying out the orders given for special examinations, dietetic revision, etc. After the few first months, visits need not be made so frequently, though it is well to encourage children to return as frequently as they desire when their interest has been claimed. At times it is necessary to send for children who have not returned within a two-month period, but this is an exceedingly rare occurrence.

The Mother's Part

Another little device of psychological value, has been the establishing of three types of admission cards for parents. Too often the long suffering parent receives little recognition for her solicitude, her devotion, and her efforts at cooperation. In appreciation of this fact different colored cards of admission are employed for those first coming to the class, those who manifest their interest and endeavor to carry out the instructions, and those who show through their children that their enthusiasm and complete cooperation have been of an unusually high standard. The mothers have recognized their promotions through changed cards with evidences of pride and understanding which have been reflected in their keener efforts to abide by the rules of the class.

In this desultory description of some of the phases of work of the Health Class I have attempted to outline its purpose and its methods. It is, in a sense, a health center that is an integral part of the dispensary system of the Mount Sinai Hospital dispensary. Its effectiveness has been increased through the splendid cooperation of all the clinics of the dispensary, the superintendent of the hospital, the Board of Trustees, the Social Service Auxiliary of the hospital, and all those whose work with the hospital has proved the importance of preventive medicine.

The Health Class is, in fine, an attempt at applying humanized and socialized medicine, employing all medical, psychological, educational, and economic measures to built up a new generation. It is founded on the positive idea of health, rather than the negative idea of disease; it visualizes physical, mental, and moral potentials; it shifts the emphasis of dispensary work to prevention rather than cure; it aims to make health contagious; its machinery is simple; its methods are diverse, but rational; its service is directed to the children, and their families. Its results are powerful for bettering and strengthening familial life, and for improving the physical mental and moral well being of the children who are the potential citizens of tomorrow.

CHAIR IN THROAT SPECIALTIES

The first medical chair in bronchoscopy and oesophagoscopy has been established in the Graduate School of Medicine in the University of Pennsylvania. It will be filled by Chevalier Jackson, M.D., of Philadelphia, an eminent authority on these subjects.

When society has 60 per cent instead of 30 per cent who have income, home, and character, a new public opinion will take from the poor their poverty by institutional measures which do what personal case-work cannot accomplish.—Patten.

Science is teaching man to know and reverence truth, and to believe that only as far as he knows and loves it can he live worthily on earth, and vindicate the dignity of his spirit.—Harvey.

ELEMENTS ESSENTIAL TO NUTRITION

THERE is current the notion that somehow out of the nutritional experience of the race appetites and instincts are developed which constitute a safe guide to secure efficient nutrition. This theory, however, does not take into consideration that instincts become perverted, that natural foods are treated artificially, that losses are entailed when foods are dried or heated for preservative or other purposes, and that foods sealed and kept for long periods may not subserve proper nutrition. To the naive view that the quantity eaten is the one important factor, has been added some general notion of the essential constituents of a ration properly balanced as to proportions of proteins, carbohydrates, fat, and mineral salts.

Food values, then, are not to be estimated on a quantitative basis, nor even from standards of energy supply. It is quite possible to eat regularly, until the appetite is satisfied, of well prepared and palatable foods and still suffer from a deficiency disease. Vague diseases of serious import may be traced to errors in diet and no adequate understanding of disturbances in health is to be arrived at without a study of food habits, the supply and distribution of natural foods, and of family budgets.

Underwood and Underwood.

Chemists of the United States Public Health Service laboratories conducting experiments in an effort to determine what vital ingredients are absent in certain prepared foods, believed to cause some of the common but still obscure dietetic diseases.

Even then a diet may be inefficient and the chemist may need to be called to demonstrate the presence or absence of vitamines, the deprivation of which may cause widespread diseases, like pellagra, beriberi, rickets, or scurvy—diseases which formerly were misunderstood and wrongly treated. The public health laboratories are continuously conducting tests and experiments to determine causes of common but obscure dietetic diseases. S. P. M.

SURVEY OF FEEBLEMINDED IN MISSOURI

The National Committee for Mental Hygiene has been invited by Governor Frederick D. Gardiner of Missouri to undertake a survey of the conditions of the feebleminded in that state with a view to ascertaining the expense of their neglect and what economies can be effected by the training and custody of such persons. The survey is under the jurisdiction of Dr. Thomas H. Haines, of Columbus, O., who has made similar surveys for the Committee in Kentucky, Tennessee, Alabama, and Missouri. Mr. C. L. Hultgren is assistant.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M OLMSTED, R. N., *Editor*

MISSOURI NURSES PLAN RADICAL CHANGES

WE HAVE always thought that Missourians had to be shown, but we know now that the Missouri nurses are taking the lead in solving the nursing problems of this country. They will soon show us all what can be done in legislative and educational matters pertaining to nursing.

A meeting of the Missouri State Nurses' Association was held in Kansas City, Mo., October 20 to 23, attended by about four hundred nurses. The program was intensely interesting and worth while. The most encouraging spirit pervaded the entire conference, the spirit of responsibility being shared by each individual nurse and not confined to just the few leaders as is so often seen at many of our meetings. There were many leaders, and many interesting discussions resulted.

The Missouri State Nurses' Association is about to launch a legislative campaign worthy of note. Miss Helen Hoy Greeley, the attorney who did such memorable work in securing rank for nurses, is in Missouri now at the invitation of the State Nurses' Association, and plans are being made for a campaign headquarters. Bills are being studied and a model one for Missouri is being prepared which will cover the raising of educational entrance requirements for schools of nursing, compulsory registration of both nurses and bedside attendants, and state inspection of schools for nurses.

Miss Sara E. Parsons is also spending some weeks in Missouri in order to secure adequate and convincing material to place before the people concerning the need of certain legislative changes. Miss Parsons, one of the best known and best informed women in the profession, has become prominent through what she has been able to achieve as superintendent of nurses of Massachusetts General Hospital. Her work in Missouri will include a complete survey of Missouri schools for nurses. The report of her findings will undoubtedly do much to interest hospital board members in the proposed legislation, and the extreme need of making the schools and the profession more attractive to young women.

Educational institutions are everywhere overcrowded, and it is logical to assume that just as soon as the people begin to realize that the shortage of nurses, which will directly affect them sooner or later, is primarily due to the fact that nursing education has never been put on a par with education for women in other fields, the entire public will favor the proposed legislation to remedy this defect.

No business man, when he develops pneumonia, wants to be cared for by a partly trained, ignorant woman who is unable to carry out efficiently the doctor's orders, or who would be unable to watch for and recognize dangerous symptoms in time to save the life of his sick baby. No woman wants to feel doubtful about the skill and intelligence of her nurse at time of acute illness or operation, and no group of women interested in developing Visiting Nurse Service or Child Welfare Nursing wants nurses so handicapped by lack of fundamental education and training that their associations fail to accomplish the much needed results.

It is safe to predict that the men and women of Missouri are going to lend a strong favorable backing to efforts of the nurses of their state to gain that status which will give the public a much finer, better prepared, more efficient nursing service for care of sick in homes, hospitals, and in public health activities.

The boards of directors of every hospital in the state should get back of this legislation and push, because it is recognized all over the United States, since at the present time the only schools for nursing which have sufficient number of student nurses are those which have the reputation of holding high educational standards. Just as soon as schools for nurses require four year high school entrance requirements, charge a tuition instead of offering a pittance, called an allowance, and give a liberal, well planned education which will attract, not repel, the average young woman of this country,—then will be solved the problem now confronting every hospital, that of furnishing adequate nursing care to the sick.

Perhaps one of the most advanced steps taken anywhere in improving educational advantages of nurses' training is the affiliation of eight schools for nurses in Kansas City with the Junior College of that city. The student nurses entering these schools get five months of practical and theoretical work at the college before taking up the nursing work in the hospital. This grouping for educational purposes and affiliating with recognized educational institutions has many advantages; not least of these in importance is the fact that it is proving a strong drawing card, and is interesting many young women in becoming nurses who scorn the training schools because they want to be educated without being loaded down with the drudgery of physical labor.

The proposed Division of Public Health Nursing for the Missouri State Department of Health is a noteworthy step in the right direction and if passed as now planned will justify all the labor and thought given it, as it will establish public health nursing in Missouri on an enduring basis.

The nurses of Missouri are making a much needed contribution to the development of nursing work at the right time. They are meeting the situation with large vision, with unbounded energy, and a fine, progressive spirit.

Nursing has received recognition within recent years as a distinct profession. This has been brought about by just such a spirit of altruism on the part of the nurses of the Nation as exists to a marked degree in the Missouri nurses. We admire the firm determination of these nurses to face the facts as they exist, to rid their state of antiquated ideas and methods that encumber progress, and we wish them great success in their efforts to establish nursing in Missouri on the high foundation and to give permanence to the progress made.

INFANT WELFARE WORK IN ATHENS, GREECE*

By MRS. CHARLOTTE HEILMAN, R.N., Athens, Greece

YOU will want to know about our work in Athens, so I will try to give some details in regard to our service. The work has developed out of a baby station that was opened by the American Red Cross during the war, and was taken over by the Greek Patriotic League, which is in fact a part of the Greek government, some time last year. The American Red Cross promised to lend them a nurse for a year to assist them in getting the work organized on a permanent basis and, accordingly, Miss Kathleen D'Olier of Rochester was sent to them, arriving in December, 1919. It was later decided that Miss D'Olier required an assistant, so I was sent in that capacity, arriving April 7, 1920.

In the spring of this year the American Red Cross closed all its work here, and the infant welfare work was taken over by the Junior Red Cross. The real responsibility for the work is with the Patriotic League, which is financing its own activities. We two nurses remained here in an advisory capacity. We take the lead in the work, and plan the routine.

How the Work Is Planned

The chief of the staff is a prominent Greek baby specialist, Dr. Dexidas, who is in charge of the work. He belongs to the Committee, and gives lectures to the volunteers and to the public for publicity. The doctor has one assistant who attends all the conferences and examines the babies. He is paid by the Greek government. There is one Greek nurse who was trained in Boston and had her Public Health course there. She is also in the pay of the Greek government. We have about twenty young Greek women volunteers, most of whom speak English fluently. Some of them are away at present for the summer holidays, but there are twelve who are still at their posts in spite of the heat, which is intense. We also have three Greek soldiers and a maid.

The main station is situated in the heart of the city, in a building that was intended for a soup kitchen. Here we have a large waiting room, doctor's office, the nurses' office, supply rooms, toilets, etc. Two additional stations are located in school buildings in outlying sections of the city. Each station is equipped with the necessary chairs, tables, scales, etc., for the conference.

Division of work is provided for by dividing the city into six districts. There are six conferences each week, so that the babies from each district attend the conference on the same day each week. Babies are enrolled as soon as possible after birth, or before birth—as we are trying to do some prenatal nursing, which is a natural part of baby welfare work. No babies are enrolled after they are three months old, a rule which we made because we want to get them before they have formed bad habits. They are discharged when they are two years old. If the mother is pregnant, a note is made of the fact and she is kept under observation, and is given a card so that she can bring the new baby to be enrolled.

Each supervisor, a graduate nurse, has her own group of volunteers, districts, and days at the Conference. The records for each district are kept in a separate file, and after the Conference each day the cards of those that were absent are looked over to ascertain the reason. Sometimes they are known to be ill, or the mother ill, out of town for a brief holiday, or perhaps transferred temporarily to the Sick Baby Clinic, which is also under the League. If no reason is known, the volunteer takes the name and, if possible, visits the baby before the next Conference.

If there is not cooperation on the mother's part, or if she fails to bring the baby regularly without sufficient reason, the baby is discharged and the card removed to the file of discharged cases. No "dead wood" is kept in the active files.

Each volunteer has her own group of babies, usually about twenty-five, and always as near together as possible, which enables her to see them more often. We are trying to cultivate a neighborhood spirit among the mothers, and, when we can it is planned to have the conferences in each district so as to increase this spirit. Every volunteer is expected to see each of her babies in its home not less than once each month, and to write up her visit on the history card at the station. She makes a full report which she hands in at the Conference of Volunteers each month. They also turn in a copy of their diaries each week. In order to keep a uniform distribution of work the volunteers are asked to enroll one new baby for each baby discharged in their districts. Preference is always given to soldiers' babies, and to those who show a disposition to cooperate, and display an eagerness to learn.

Conferences Held Daily

The station is open from 8:30 to 12 daily, except Sunday or important holidays. A soldier is stationed at the door to give a number card to each mother as she enters. She then passes to the desk, where she shows a small card which is dated by the soldier, who removes the record card from the file and dates it. She then passes into the waiting room. As soon as the mothers are assembled, the Greek nurse gives them a short talk on the care of the baby. She repeats the same talk every day for a week, so that each of the mothers may hear it. The next week her subject changes. For example: one week the subject will be "The New Born Baby;" the next week the nurse will talk on "The Bath," and the next on "Feeding," etc.

After the talk the mothers undress the babies and, according to their numbers, stand in line to have the babies weighed by one of the volunteers. The supervising nurse sits by the scales and looks the babies over from head to foot, questioning the mothers as to diet,

*Excerpts from a letter written by a member of the staff under date of August 1, 1920.

sleep, the condition of the bowels, etc. If the child has lost weight, or any change is indicated, we send it into the doctor's office. I have recommended that a doctor should be there in the place of the supervisor, but at present there is none available. Ill babies are transferred to the Sick Baby Clinic.

We have a number of layettes that were given by the American Red Cross, so that practically every baby is given an outfit, which pleases the mothers very much. We usually do not give the things until the baby has been in regular attendance at the conferences for some time, so that we can tell whether the mother will cooperate or not. The volunteers are taught how to dress the babies. The Greeks dress their babies the same as the Italians, that is, with a swaddling cloth and fascia. We discourage the use of the fascia when the child is in bed, but we understand why they want it when the children are carrying the baby about.

There is a volunteer in the doctors office to assist him and keep the records. We change the work of the girls from week to week so that they have the opportunity to do everything. As a rule, the volunteer attends the Conference only on the day when her babies come, but they are always ready to come on extra days when they are needed to help out. On other days they visit in the homes—usually one day a week, sometimes oftener—or go to clinics or agencies about some of their babies or

Such candidates as these children, who are waiting for the nurse, for the service of the child welfare service at Athens, Greece, are the chief argument in favor of organizing the work on a permanent basis.

other members of the families they visit. They are taking a very intelligent interest in the social side of their work. From time to time the volunteers are accompanied by the Supervisor.

They are wonderful young women, broad minded, intelligent, and they have a splendid grasp of the work and its meaning. They are remarkably faithful, which makes it evident that they are going to continue the work after we leave. Some of the young ladies are doing the work of friends who are away on their holidays, and we appreciate that work undertaken in such heat is not a mere fad, but is evidence of the real interest that they are taking. We are proud of them, and very eager for some of them to go to America or England to take hospital training. They have taken an intelligent interest in the lectures they have had, and they read everything we can give them. They are beginning to realize what sort of women nurses should be.

Nursing Standards Have Suffered

There are no training schools here that attract the right sort of recruits, and the standard of nursing and nurses has not been high. There are a few who have been trained in England or America, but it is rather natural that American nurses should make more impression on the people—perhaps we are more aggressive, while the Greek nurses are hampered by a consciousness of the old prejudice against women who are paid for their work. I was much pleased when the chairwoman of the Committee told me a few days ago that the example of the American nurses has had a splendid effect upon the nursing situation in Greece; that the people here have

This little waif is on her way to the Child Welfare Station, where both mothers and babies are sure of interest and sympathetic care.

learned that being a nurse, even being paid for one's services, is not incompatible with being a nurse.

These young lady volunteers are members of the best families here, and they therefore have the right social contact to interest the best people in the work. The work of volunteers is criticized exactly the same as that of our pupils in Rome, and they take it in the right spirit.

There is no good trained leader to take up the work when we leave; one of our workers is excellent, but she is young, and has not had enough experience to go on alone with the volunteers. I wish very much that the Junior Red Cross would allow us to remain another year, until the work is a little more firmly established. We have had several new volunteers who have begun work since the hot weather began, and when the holidays are over, and it is cooler, others will join us. Naturally, only those that are really worth while would hold on through this heat.

How the People Live

The people with whom we work are very poor, not because they are lazy, but because there is so little work

Almost every garden has a well, simply stoned up. There are many open cisterns. Everywhere there is a lack of sanitary supervision. The sickness rate is high and the infant death rate is given as one in four.

and the wages are so low. There are practically no raw materials, and no fuel for manufactories. The soil is very dry, and there is no water for irrigation near the

city; therefore, there is waste land all about that should be cultivated for gardens. Food is high, milk is scarce and very expensive. There is more goat's milk than cow's milk, because the food for cows is too expensive, while goats pick their own on the mountain side. I am making up a table of rents, wages, etc., in my districts, but my records are not yet completed. The average rent will be about 20 drachmae (a drachmae is about twenty cents) a month, and the average wage about 12 drachmae per working day. Milk for a baby costs at least 2 drachmae per day, and other foods are just as expensive.

The houses consist almost invariably of one room, of mud, brick, or stone, sometimes plastered, sometimes only whitewashed. The roof is usually very low, of tile which is visible from the inside, and the single window is usually very small.

Clothing is even higher. A pair of the cheapest canvas slippers costs 22 drachmae. There is some kind of law governing the age at which children may go to work, but as a matter of fact, they go whenever they can find work.

In my districts the homes consist almost invariably of one room, of mud, brick, or stone, sometimes plastered, sometimes only whitewashed. Tile roof, visible from the inside, earth floor—occasionally wood or cement—one window, and one door with a transom. Sometimes the roof is very low and the window very small, so that the room is damp and dark. The furniture consists of one bed, and a pile of bedding that is spread on the floor at night for the children, a small table, two or three chairs, almost always a little baby bed, a trunk or box, and occasionally a sewing machine, as some of the women take sewing for soldiers or for factories. There are always a few religious pictures and a lamp.

On the whole, I find the homes neat and tidy, with some effort made toward coziness. There is often a little vine or flower of some kind, and perhaps a tree in the yard. There are some advantages in these homes; they are at least not crowded together and, as they are almost all one story, there are no dark passages or stairways. The majority of the poor homes are in the outlying section of the city, on the hills, where they are assured good drainage, a beautiful outlook—which the people seem to appreciate—plenty of sun, and a breeze. Most of the houses are in small groups; each house has perhaps four or five rooms—each occupied by a separate family—all opening into a garden which is uncultivated and is usually surrounded by a mud brick wall. The children all play together, and the women work together. Very often they have a sort of outdoor kitchen which they use in common. Sometimes they each have a little burner—often made out of a Standard Oil gasoline can; but they all do the cooking in the yard. They have very few dishes and many of them do not sit down at the table. Bread is the main article of diet, but they also eat vegetables.

The water supply is very poor. In these outlying districts almost every garden has an open well simply stoned up. Not far away, perhaps within twenty feet, is the toilet, which sometimes has a cemented cesspool, but more often is simply a little hole in the ground, or possibly not even a hole. There is never a toilet seat. Usually we find these places neat, and remarkably free from odor, as most of the people throw lime about from time to time. There are not as many flies as are seen in America, but there are many mosquitoes and much malaria, though it is not apparent where the mosquitoes breed, unless in the many open cisterns about the city.

Few Bed Patients in Homes

Those who are ill usually go to a hospital, so that we do not often find bed patients in the homes. There is much tuberculosis. The infant death rate is given as one in four.

There is much to be done here. The people seem to realize it, but the country has been at war so much that it is far from rich. They need better schools, better houses, and more work almost more than anything else.

Many difficulties are encountered in directing the feeding of the babies. Mother's milk is, of course, advised and insisted upon when possible. Some have supplementary feedings of goat's milk if the mother can buy it or, if it seems imperative, the League buys it. Ordinarily the supplementary feedings are of condensed milk which is furnished by the League, not that we approve of the condensed milk, but it is the best that we can do just now. The addition of other foods and the general routine of feeding is about the same as that to which we are accustomed.

There are certain superstitions here more or less the same as those met with in Italy. The people believe in "the evil eye" and not infrequently give it as the cause of death of the babies. Many of the babies wear a string of blue beads around the wrist to protect them from this influence. Horses also wear a necklace of blue beads for the same reason. One of the mothers who has nephritis believes firmly that her blue beads will make the albumin disappear from her urine.

We have been trying to map out a program for the future, that is, for the time when we must leave, but as yet we have not arrived at anything that is satisfactory.

On the whole the houses are neat and tidy. Usually a vine or flower of some kind, or a tree, shows the effort to make them cosy. The houses are in small groups. The children all play together, the women work together, and often they have outdoor kitchens which they use in common.

We have thought of a course similar to that which we gave in Rome, but there are not the right kind of pupils available. The young ladies who are doing the work now are of such a fine type that we do not want to lower the standard already set. It seems that it might be better to try to find a good leader and go on with the volunteers, since they have done so well. We see greater interest and capability each month and feel that, if we do keep on, some of them could be induced to go away and take training. Some scholarships would be required

in such a case, for some of them have not a very large income and could not afford the expense of the trip and the training for three years, though they would probably accept a scholarship. It only remains for someone to take the lead and the rest will follow.

Much Interest in the Work

Besides our work, our life is full of variety and interest. There are about one hundred Americans, members of the Legation Staff, the Consul and his staff, the Young Men's Christian Association workers, the Standard Oil people, and a number of other Americans in import trade. At present there is also a group of American engineers who are working on a water and sewage system for Athens. These engineers have asked us for suggestions as to the most practical way to make a water and sewage system reach all the poorer homes, consisting of one room only, in which it is obviously impossible to have individual taps and toilets.

We have an American Club which has its regular meetings at the Young Men's Christian Association, and we have many dinner parties and picnics. We go sailing, bathing, and have very good times. Many of the men have their wives and families with them, so there are plenty of both sexes. The sea is only a few miles distant—it is within sight in almost all parts of the city, and there is an excellent electric train service every few minutes. There is a wonderful sandy beach, and the most beautiful water imaginable. We can also take a steamer and go for a little holiday on Sunday, returning in the evening, or hire an automobile and go to some of the places of historic interest. On one such occasion we went to Delphi, a most beautiful spot aside from the fascination of its history. Another time, when there was a church holiday, we went for a two day trip to Corinth and down through Peloponnesus, visiting the ruins of Mycenae, Argos, Tiryns, and, most delightful of all, Epidaurus, the most celebrated seat of the cult of Aesculapius, the god of healing. It was here that the sacred snake had its origin. If the place were reconstructed today on the original plan, we would call it an up-to-date sanatorium. The hospital proper was an open air pavilion and there were the gymnasium, baths, games of all sorts, musical exercises, a theater which is almost perfect today and still the favorite model. The one at Berkeley, Calif., is modeled after it. There are also temples for worship.

The buildings were of the most precious marble and of the finest workmanship, and the setting is magnificent, with the most beautiful mountains on all sides and lovely coloring. The atmosphere is so clear and invigorating, as it is near enough to the sea to have the full effect of the sea air. It is no wonder that Hippocrates made a success of his profession, as it was in that spot that he was a student and a doctor. It is perfectly understandable that his tuberculous patients would recover by following his advice to "Take a cow and go live in the mountains."

THE EVOLUTION OF PUBLIC HEALTH NURSING

By ROSE M. EHRENFELD, Supervisor of Public Health Nursing, State Board of Health, Raleigh, N. C.

PUBLIC health nursing is the latest development in the national health movement. Public health nurses were at work here and there before the war, but conditions either revealed or brought about by the war have given to public health nursing such a great impetus that the public health nurse suddenly finds herself the most important single factor in bringing to the citizens of this country an "equal chance for equal health." More than this; she is bringing to the citizens of this country an opportunity for health that is as big as other opportunities that knock at our doors every minute of every day and that we have come to accept as a matter of course.

The work of the public health nurses in cantonment zones and devasted countries was such as to cause the Federal Government to take cognizance of this particular branch of nursing, and the United States Public Health Service created a division of public health nursing; issued a bulletin thereon for distribution from pulpits on National Health Sunday; and their first reconstruction bill before Congress called for provision for community nursing.

Since 1859, when William Rathbone and Florence Nightingale established in Liverpool the first District Nurse Association, public health nursing has gradually and steadily developed. This development has been along two distinct lines.

The first of these has been from the limited field of remedial case work toward the preventive and educational phases, including always the curative. This remedial case work was originally carried on by a benevolent or relief society which frequently gave material aid with nursing care. The natural outcome of the giving of this material assistance was that the public health nurse became known as the "charity nurse" and only those who openly admitted themselves to be very poor were willing to accept her aid.

The second conspicuous line of development in public health nursing has been the gradual change from one type of administration to another. This type of work was originally carried on by a board of representative men and women who undertook the work as a community enterprise for community betterment. They offered professional nursing service to both pay and free patients and the sphere of their activity was limited only by local geography and the lack of transportation facilities. They cooperated with the agency which rightfully supplied material relief.

At the present moment, many changes and re-

adjustments are taking place in the field of public health nursing. Two facts stand out: (1) a nation-wide interest in public health is rapidly developing; (2) there is an alarming shortage of nurses to meet the demands of this growing interest.

Consider the growing interest. In many localities, already existent associations are reorganizing along progressive lines. In many states, provision for nursing supervision is being made with certain standards for nurse, nursing service, and record keeping. Many states are creating bureaus or divisions of public health nursing as a part of the state boards of health. These bureaus are on an equal basis with other bureaus. Other states are providing for state directors or supervising nurses under the state board of health. The twelve states that have adopted one or the other of these post-war programs are: Alabama, Connecticut, Kentucky, Maryland, Minnesota, New Jersey, New York, North Carolina, Ohio, South Carolina, Virgina, and West Virginia. The ultimate aim is to provide public health nurses in a certain proportion to the population of each state, these nurses to work on a standardized basis. Of paramount importance will be the educational and preventive program. This plan will apply equally to remote and congested communities, equally to Texas and New York. Many states have passed laws permitting expenditure of municipal and county funds for public health nursing, while three have legislation providing for a nurse in every county.

Register Industrial Nurses

The latest evidence of increasing interest comes from the Department of Labor which contemplates the establishment of a registry for nurses who have special qualifications and training for industrial nursing. This comes under the Division of Industrial Hygiene and Medicine, the personnel of which has been detailed from the United States Public Health Service to the Working Conditions Service of the Department of Labor.

The Federal Children's Bureau's $8,000 contract with the National Organization covers three experiments in public health nursing made in rural care of mothers and babies—one in an Illinois county, predominatingly "white population"; one in Louisiana, predominatingly "negro"; and one at Wind River Reservation, Wyoming, a predominatingly Indian county. The first year's work will probably be issued as a Children's Bureau bulletin and will not only form an excellent model program for county work but will probably be a force in securing state and Federal legislation to promote public health nursing. Four states already have public health legislation and are directing the service from private agencies to a governmental activity, realizing that nursing is not merely a private or individual service, nor rightfully the function of separate small communities against the menace of disease.

In 1901, there were fifty-eight associations doing public health nursing, with 130 nurses. In 1916 there were 1,992 organizations in 1,496 cities and towns, with 5,152 nurses. With such a retrospect, what may we not expect from the sudden great impetus given by the war?

Plans to Recruit Nurses

Let us consider what is being done to foster this increasing interest in public health and to meet its demands for nurses. Numerous plans are under discussion for recruiting young women into the ranks of the nursing profession and a few of these plans are taking definite shape.

The American Red Cross, an organization standing for a high type of efficiency along nursing lines in both war and peace, is making a threefold contribution to the cause of public health nursing: (1) Changing its Town and Country Nursing Service to a Bureau of Public Health Nursing with a definite policy as to standard of work and qualifications of nurses and providing for thirteen divisional directors; (2) authorizing in communities where no such service exists or is contemplated, the initiation of public health nursing activity, supporting it by chapter funds until support by municipal or state funds can be secured for it, by which provision there are in North Carolina, in four counties, specially trained nurses who are doing for human lives what scientific agriculture is doing for crops; (3) contributing, in addition to a substantial loan fund, a scholarship fund of $100,000 for the purpose of giving to nurses—and especially those returning from war service—a public health nursing course. These scholarships are helping to meet the shortage of public health nurses and also contribute a standardizing influence in the field of public health nursing, because only women who have had special training or the equivalent in experience are eligible through the Public Health Nursing Bureau of the American Red Cross.

Other scholarships are being offered by various organizations. The National Organization for Public Health Nursing, founded 1912, with a membership of three thousand and now having eight thousand members, represents a revolutionizing factor of professional and lay people. It is raising a $150,000 scholarship fund to supplement previous training or experience of graduates and prepare them for public health nursing. It is

also placing literature for distribution to public health nurses, and others interested, at library centers throughout the United States. The Metropolitan Life Insurance Company is providing scholarships and territorial supervision. The General Federation of Women's Clubs is raising from one to three scholarships in some of the states.

Combined courses in public health are being given at universities, affiliating for training in field work with well established nursing organizations; and there are one hundred hospitals now giving to selected seniors a four months' course in some public health nursing school.

All of these opportunities for special preparation put it within the reach of a graduate nurse with high school education to enter the field of public health nursing. It is noteworthy that many college women are entering various hospital training schools, appreciating the possibilities of this field of large horizon and visions of service.

The Need of Special Training

Yet there is a tendency on the part of the nurse to enter this field without special training. This is undesirable from every point of view, unless she is working directly under a well qualified supervising nurse. In the first place, the nurse who lacks special training is at a disadvantage, for the community will rightfully expect service she is unprepared to render and results she is unable to effect. Any community contemplating the establishment of a public health nursing service would do well to delay instituting the work until a woman especially trained for public health work can be secured or a nurse of the locality's choice takes advantage of a scholarship to prepare herself for the field. This is the only way the work can come up to the standard of the Red Cross, the Public Health Bureau, or the National Organization for Public Health Nursing. With rarest exceptions anything less than a standardized work represents a superficial, unsatisfactory, not to be recommended endeavor rather than a contributing force for community health.

It is becoming increasingly evident that, if the public health nursing movement is to acquire its full development, the sick of moderate means must be cared for at a cost which will not leave them financially crippled upon recovery. Consider, for a moment, the convention at Cannes, where an international system of public health service was discussed and at which it was the purpose of the late Miss Delano to be present. May her memory be a constant reminder that we have a life to live as well as a living to make and her sacrifice be our inspiration to prepare ourselves to render a new type of national service that will furnish a high type of nursing service according to the need rather than the income.

Public health nursing has become one of the strongest forces for Americanization, reaching into the homes and teaching the foreign mothers how to interpret sanitary codes and obey quarantine laws; how to select and use American food.

It represents the field of work that is reaching some of the "90 per cent of the sick outside of institutions" with nursing care in their homes. It is extending to the masses prenatal, postnatal, tuberculosis, school, industrial, communicable disease, and general community nursing. In so doing it represents the most important single factor in our national effort to check the slaughter of innocents by the kaiser of ignorance. It represents the instrument by which Democracy's latest vision, "equal opportunity for health" is being practically applied and by which the light of modern science and the warmth of human sympathy is spreading into every corner of the world.

Because the public health nurse has made possible the universal democratic application of public health work, Dr. Wm. H. Welch says: "America has made two great contributions to the cause of public health—the Panama Canal and the Public Health Nurse."

RED CROSS CLINICS IN SALONICA

Nearly fifteen hundred maimed and halt and blind are treated monthly at the American Red Cross Dispensary at Salonica, Greece, under the direction of Dr. William J. Hillas, from Chattanooga, Tenn. Dental work is provided in connection with the dispensary, and a creche and maternity hospital are maintained in connection with a local woman's society. Of the cases that come before Dr. Hillas, 25 per cent are eye troubles, 25 per cent are malaria, and the rest are under miscellaneous classification.

INSIDE HOSPITAL AND FIRST AID CORPS

The access of miners to hospitals varies greatly. They rarely resort to hospitals for sickness. Foreigners are more inclined to take advantage of hospitalization than is the average American. This emergency hospital is stationed right in one of the mines of the Kingston Coal Company. First aid is well prepared for at the mines, but quarters for the sick are lamentably scarce.

MEDICAL INSPECTION OF SCHOOLS IN PENNSYLVANIA

By GEORGE K. STRODE, B.S., M.D., International Health Board, New York City, Formerly Chief of the Division of School Health, State Department of Health, Harrisburg, Pa.

ALONG with other special health activities in the United States, school inspection was given a tremendous impetus by our experience in the great war. Today there seems to be a more general appreciation of the intrinsic and extrinsic worth of such work than three years ago. Doubtless the findings of the draft boards were to a considerable extent instrumental in this rapid spread of interest. The ultimate result of awakened public interest, namely, more and better school inspection, has not so far resulted. As formerly, the bulk of the work is still done in the larger cities. School inspection carried out on a state wide plan is the exception rather than the rule, and for this reason it seems appropriate to discuss Pennsylvania's experience. It will be our object to point out our shortcomings and failures as well as our successes.

State Wide School Inspection

Since 1911 the laws of the Commonwealth of Pennsylvania have provided for medical inspection in the public schools. Prior to the enactment of this law the State Department of Health had carried out an experimental inspection in three large and populous counties. This inspection, comprehending as it did rural districts alone, showed that less than half of the pupils could be classed as normal. The law makers were probably influenced by the results of this experiment, since they provided for medical and sanitary inspection of schools in the School Code which was adopted the succeeding year. Prior to the enactment of the Code, Philadelphia had already been carrying out medical inspection in its schools since 1898 and Pittsburgh since 1910.

In Pennsylvania each city, incorporated borough, or township constitutes a separate school district and each district is controlled by a local board of school directors. Cities with a population of five hundred thousand or more constitute districts of the first class; we have two such school districts, Philadelphia and Pittsburgh. Districts

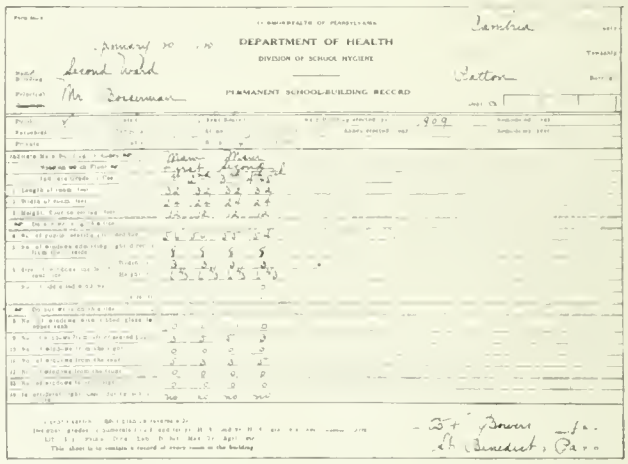
DIVISION OF SCHOOL HYGIENE
TEACHER'S RETURN REPORT

Fig. 1.—This report incorporates data gained from the examinations through which the pupils in the public schools of Pennsylvania must pass.

with a population between five hundred thousand and thirty thousand are second class; there are fifteen of these districts in Pennsylvania. There are one hundred and ninety-one districts with a population ranging between thirty thousand and five thousand designated third class. Lastly, there are 2,385 districts with less than five thousand population; these so-called fourth class districts are almost wholly rural.

As originally enacted, school inspection was compulsory only in first and second class school districts. The boards of school directors of the third and fourth class districts might elect to have medical inspection, but it was not made compulsory. Advantage of this option was taken



DEPARTMENT OF HEALTH
DIVISION OF SCHOOL HYGIENE

Fig. 2.—These data form a part of the permanent record of the sanitary survey of the school plant. A follow-up record of each fourth class school is kept on file in the central office.

by 1,617 of the 2,385 fourth class districts and by most of the 191 third class districts during the first inspection in 1911-1912. Year by year the option was less and less used until in 1918-1919 but sixty-three fourth class districts and ninety-two third class districts rejected inspection. This reflects a healthy state of mind on the part of school directors so far as an appreciation of the value of school inspection is concerned. In view of the general acceptance of medical inspection, the law was amended in 1919 so that it became compulsory in all districts.

The School Inspection Law

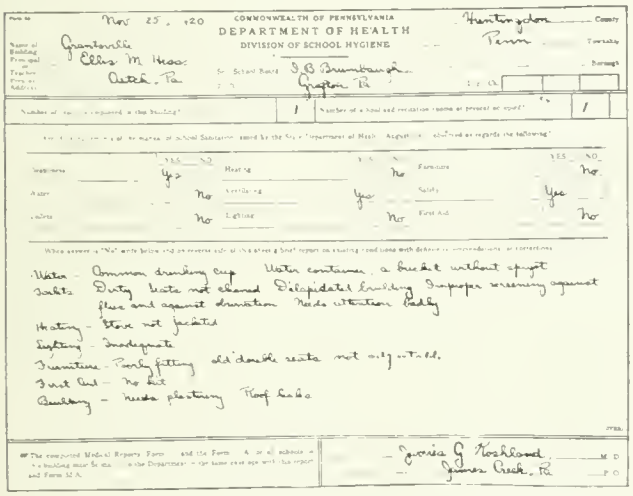
In every school district which is required to provide medical inspection for its public schools the secretary of the school board or the superintendent must report annually to the Commissioner of Health the names of the medical inspectors; if medical inspection is not furnished within a stated period, the Commissioner of Health is required to appoint an inspector and fix the compensation for the same which shall be paid by the district.

The law requires that at least once each year the medical inspector shall test and examine all pupils in the public schools, giving special attention to defective sight, hearing, teeth, or other disabilities and defects specified by the Commissioner of Health in his directions for medical examination of schools. The requirement that the Commissioner of Health shall give directions for the med-

ical examination of schools is a wise provision and of the greatest importance from the administration standpoint, as it makes possible standardized work in every district of the Commonwealth.

The medical inspector is required to make to the teacher or, if the board of school directors so specify, to the principal or district superintendent of schools, a written report concerning all pupils found to be in need of medical and surgical attention and to give careful directions concerning the care of each pupil who needs special care while in school. The teacher, principal, or superintendent must keep such reports until the end of the school year and shall carry out as carefully as possible the directions concerning special care of pupils while in school and shall promptly send a copy of the inspector's report upon each pupil to the parents or guardians thereof.

Further, the inspector must report to the Commissioner of Health the results of examinations. Special blanks are provided for such reports. These reports enable us in



COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF HEALTH
DIVISION OF SCHOOL HYGIENE

Fig. 3.—Nine major topics engage the attention of the sanitary inspector of schools, the minimum standards to be met being established in a prepared manual of school sanitary standards.

a measure to appraise the worth of work in every school district.

In addition to the above mentioned duties of school inspectors it should be stated that he must make a careful examination of all privies, water closets, urinals, cellars, water supplies, drinking vessels, utensils, and such additional examinations of the sanitary condition of the school buildings and grounds as the regulations of the State Department of Health direct. To facilitate the inspection and maintain a reasonable standard of excellence, the State Department of Health has issued a manual of school sanitation which fixes the minimum requirements of sanitation for the school plant.

School nurses are authorized by the law but are not made mandatory. This is unfortunate, since the effectiveness of the work is so dependent on nursing service.

Any school district may provide for the care and treatment of defective eyes and teeth of pupils. This is done in many of the larger districts, which also care for the tuberculous, the malnourished, the gravely retarded pupils, and those deaf or affected with speech defects.

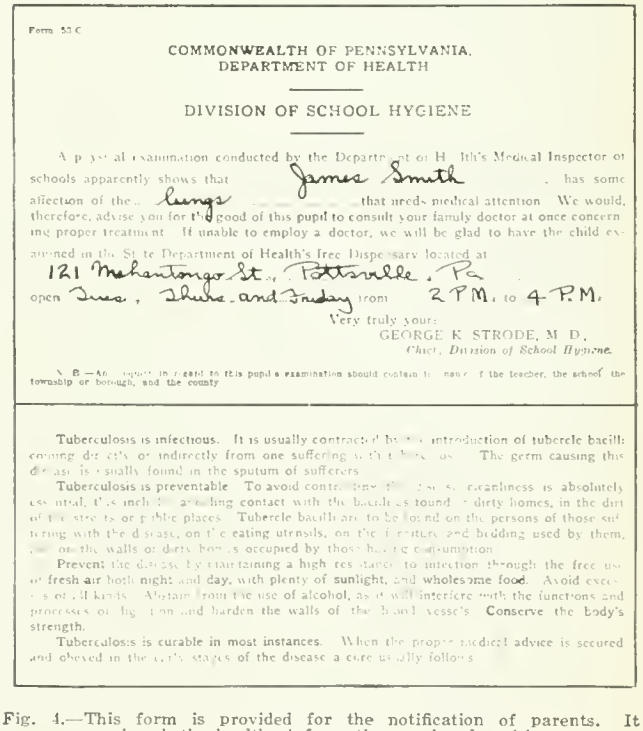
Cost of School Inspection

The funds required for medical inspection in first, second, and third class districts are provided by the school boards. The sum budgeted for health work in the schools, including the item of salary for the medical examiner, is determined by the individual districts according to local conditions. In the first class district examiners receive from $900 to $1,800 for the school year; they work during school hours only. The examiners in second and third class districts are usually part time men and receive compensation amounting to from fifteen to fifty cents per pupil.

The Legislature sets aside annually a fund of $125,000 for the distinct purpose of providing school inspection in the fourth class districts. Though this sum seems large in the aggregate, it is just sufficient to enable us to fix the rate of $6 for each single room school or the first room in a multiple room school, and $4.50 for each additional room in a multiple room school. The average yearly earnings of an inspector are $125. No transportation is provided; the inspector at his own expense may have to travel ten or twelve miles to reach a school; yet, notwithstanding the meager remuneration, hundreds of our inspectors have been willing to do the work year after year; this is a splendid commentary of their interest in preventive medicine and community welfare.

Administration in Fourth Class Districts

Because of the enormous geographical area covered by the fourth class school districts, the problem of administration is most difficult. Nothing is required of the inspector in these districts except to provide each pupil one examination per year and to make a careful sanitary survey of every school plant. The problem of communicable disease control is almost entirely without the province of our inspector, and the follow-up work he is not even called upon to supervise, both of these important problems being cared for by other agencies. The inspector is provided with printed forms, instructions, and a list



Form 53 C

COMMONWEALTH OF PENNSYLVANIA.
DEPARTMENT OF HEALTH

DIVISION OF SCHOOL HYGIENE

A physical examination conducted by the Department of Health's Medical Inspector of schools apparently shows that James Smith has some affection of the... lungs that needs medical attention. We would, therefore, advise you for the good of this pupil to consult your family doctor at once concerning proper treatment. If unable to employ a doctor, we will be glad to have the child examined in the State Department of Health's free Dispensary located at

121 Mahantongo St., Pottsville, Pa.

open Tues., Thurs. and Friday from 2 P.M. to 4 P.M.

Very truly yours,
GEORGE K. STRODE, M. D.,
Chief, Division of School Hygiene.

N. B.—Any report in regard to this pupil's examination should contain the name of the teacher, the school, the township or borough, and the county.

Tuberculosis is infectious. It is usually contracted by the introduction of tubercle bacilli coming directly or indirectly from one suffering with the disease. The germ causing this disease is usually found in the sputum of sufferers.

Tuberculosis is preventable. To avoid contracting the disease, cleanliness is absolutely essential. This includes avoiding contact with the bacilli as found in dirty homes, in the dirt of the streets or public places. Tubercle bacilli are to be found on the persons of those suffering with the disease, on the eating utensils, on the furniture and bedding used by them, and on the walls of dirty homes occupied by those having consumption.

Prevent the disease by maintaining a high resistance to infection through the free use of fresh air both night and day, with plenty of sunlight, and wholesome food. Avoid excesses of all kinds. Abstain from the use of alcohol, as it will interfere with the functions and processes of digestion and harden the walls of the blood vessels. Conserve the body's strength.

Tuberculosis is curable in most instances. When the proper medical advice is secured and obeyed in the early stages of the disease a cure usually follows.

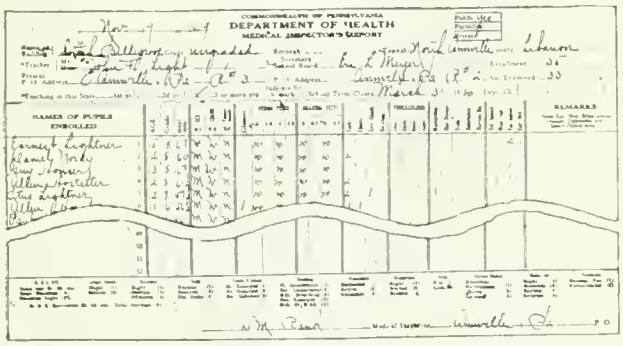
Fig. 4.—This form is provided for the notification of parents. It carries both health information and admonition.

of the school districts he is to examine. His routine duty may be summarized as follows:

Upon arrival at the school house he consults with the teacher, explains what he will do, and proceeds with the work. A short talk of five or ten minutes on some health

theme in accordance with a syllabus previously forwarded by the Department is first given. The inspector then begins to examine the pupils. Form 51, the Medical Inspector's Report, is made use of in recording pertinent data (Fig. 1).

With the exception of vision and hearing, records of defects only are made. Numerals are used to designate defects and the key at the bottom of the form defines the significance of these symbols. An important shortcoming in the method of recording defects which we have used lies in the inability of the central office correctly to interpret each inspector's reports. Serious impairment of breathing to one inspector might be regarded as slight impairment by another inspector. Parents are notified concerning serious impairments, but for slight impair-



COMMONWEALTH OF PENNSYLVANIA
DEPARTMENT OF HEALTH
MEDICAL INSPECTOR'S REPORT

Fig. 5.—The central office sees to it that the reported defects in children are made the object of follow-up work on the part of the teacher, a system of value in lieu of a school nurse.

ments no notices are forwarded. Both inspectors above referred to might feel that the defect required treatment, yet only the record of serious impairment would result in a notification. In the future, therefore, we will divide all defects into three groups, as follows: (1) Those minor ailments or defects which do not require a recommendation for treatment; (2) remediable defects for which treatment is recommended; and (3) irremediable defects for which treatment is not recommended. Misunderstanding and misinterpretation will thereby be largely overcome and the service materially improved.

The inspector proceeds with his examinations in accordance with the sequence of headings on the examination blank. It has been felt that the child's confidence could more readily be won by first testing vision and hearing, thereafter those examinations requiring more of the child's cooperation being carried out. After all the pupils have been examined, the inspector proceeds with the sanitary survey of the school plant. A follow-up record of each school building in the fourth class districts is kept on file in the central office. The record card used is posted annually and provides space for a ten year period. Such data as window area, floor area, cubic air space, and position of windows are not included on the annual report. These measurements have been made and form part of a permanent record; they were originally submitted by the inspectors on the form shown in Fig. 2. As before mentioned, the inspector is guided in his sanitary survey by a set of minimum standards recorded in the "Manual of School Sanitation." On the blank form used for the sanitary survey of the school plant (Fig. 3) there are nine major topics to engage the inspector's attention,—cleanliness, water, toilets, heating, ventilation, lighting, furniture, safety and first aid. If the requirements are met for any particular item, a check mark is made in the "Yes" column opposite the item; if the requirements have not been met, a check is made in the "No" column and a brief synopsis of defects, with recommendations for correction thereof, is entered in the space provided on the form.

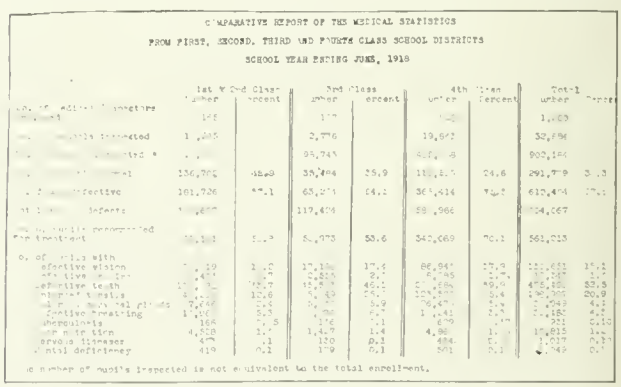
The System of Notification

Upon completion of a school the inspector forwards his reports to the central office, where they are carefully reviewed and errors corrected. From the medical reports notices are written to the parent or guardian of every pupil reported having a remediable defect. A typical notice is shown in Fig. 4. At the same time the parental notifications are written, a report is made to the teacher (Fig. 5) on which are listed the pupils for whom treatment is recommended as well as the part of the body defective. The teacher is required to return this report at the end of the school year with notations as to treatments secured and results attained. The teacher thus becomes a follow-up agent in her own school. The possibilities in such a method are necessarily limited, and yet it recommends itself as the simplest device where no school nurses are available. As a matter of fact, this device has shown us that between 20 and 24 per cent of the pupils reported for treatment have had at least one of their defects corrected. During the past year an attempt has been made to utilize such agencies as the community nurse, Red Cross nurse, and lay committees to do follow-up work in the schools. Several of such agencies are now functioning and it is hoped their work will materially increase the number of corrections.

The defects in the school plant, a list of which is obtained from the Sanitary Survey Form, are reported to the school board and instructions issued to correct the same. The number of corrections by this method, though considerable, is still far from satisfactory, and it seems likely that it will be necessary to use the threat of withholding state appropriations to accomplish our end and provide a reasonably sanitary environment for all the school children.

Results of Medical Inspection

For the purpose of brevity as well as ready comparison the statistics from all school districts in the Common-



COMPARATIVE REPORT OF THE MEDICAL STATISTICS
FROM FIRST, SECOND, THIRD AND FOURTH CLASS SCHOOL DISTRICTS
SCHOOL YEAR ENDING JUNE, 1918

Fig. 6.—For purposes of comparison the statistics from all school districts are grouped in one chart. The work is standardized and the results can be dealt with as a unit.

wealth have been grouped together in one chart (Fig. 6). The statistics from first and second class districts are combined; there is no marked variation in the type of work done in these districts, and in consequence the statistics can be dealt with as a unit.

The outstanding feature in this chart is the marked excess of physically defective pupils reported in the rural

districts as compared with the urban districts. There are about 18 per cent more defectives in fourth class districts than in the first and second class districts. The questions at once arise, is this a true measure of actual conditions? Does rural life result in the development of such a disproportionate number of physically defective children? Before answering, it will be well to consider certain observations that have a more or less direct bearing on the problem.

(1) The inspectors in the rural districts have more time for careful inspection, with the possible result that more defects may be detected. In the urban districts the inspectors average 1,930 pupils a year, while in the rural districts they average but 520 pupils. On the other hand, it must be kept in mind that the city inspector who is inspecting day in and day out becomes very expert and can actually examine with care more pupils in a unit of time than the part-time rural inspector.

(2) The lack of objective standards which apply in urban and rural districts alike, militate against the accuracy of comparisons. However, when we compare such a defect as that of vision for which we have an objective standard, as supplied in the Snellen chart, a standard that is used in all districts of the Commonwealth, we still find the rural districts report more defects than the urban, as 7.7 per cent more pupils have defective vision in the former districts.

The probable explanation of the disproportionate number of defects found in rural districts is that less effort is made to correct them and prevent their development than is the case in urban districts. The health conscience of people has reached a higher plane in the urban districts; the people more generally appreciate the value of good health and they more generally utilize agencies that tend to produce good health; further, they are fortified against disease and physical impairment in a score of different ways that have not as yet been generally adopted in the country districts.

A comparison of the number of defects which are annually corrected in the first class districts and the fourth class districts throws still further light of the question of relative frequency of defects in urban and rural communities.

Of the 307,295 pupils in fourth class districts recommended for treatment in the year 1917-1918, 63,186, or 20.5 per cent, were reported treated. On the other hand, in a first class district such as Philadelphia, 58,806, or 63.5 per cent, of the 92,615 defective pupils for whom treatment was recommended had received treatment. The marked difference in the percentage is certainly attributed to the uncertainty and meagerness of follow-up work in rural districts as compared with that in our large cities. There is a lack of hospitals, dispensaries, and social agencies concerned with child health in the rural communities and, further, those corrective facilities that may be available are not placed at the disposal of the school child for the correction of his physical defects. All of these factors operate to limit the number of corrections obtained.

With a very considerable yearly reduction in physical defects in the cities and a very small reduction in the rural districts, it is obvious that there will be an accumulation of defects in the latter districts which in the course of years will make it appear as though the rural communities were producing large numbers of physical defects as contrasted with the cities.

The author feels thoroughly convinced that if the same corrective and preventive measures could be applied to the same extent among rural and urban school children there would be, within a few years, decided similarity in the number of defects reported for the two districts.

It would seem that the big factor operating to the disadvantage of the rural communities is that of an accumulation of defectives rather than an excess of production of defectives. Such an accumulation would, of course, include those secondary defects arising from older and more primary defects.

Results of Sanitary Inspection

As before mentioned, a sanitary survey of every school plant is made at least once a year. The results of these surveys show that the rural districts are far from what they should be. The perfect school plants in the country districts are rarities. The following table (Fig. 7) will

DEFECTS CORRECTED THROUGH SANITARY SURVEY OF SCHOOLS

School Year Ending June 30th

School or class rooms inspected	1916 20,077		1918 20,523		Diminution or gain
Air space below requirement	3,382	16.8 %	2,771	13.5 %	3.1 % Dim.
Dark window shades in use	10,980	54.1 %	8,456	41.2 %	12.9 % Dim.
Dry dusting practiced	4,787	23.8 %	2,933	14.2 %	9.4 % Dim.
School buildings inspected	12,558	61.4 %	12,155	59.2 %	2.2 % Dim.
Multiple room buildings	2,560	12.8 %	2,714	13.1 %	.7 % Gain
Single room buildings	10,038	49.4 %	9,431	46.9 %	3.. % Dim.
Unjacketed stoves in use	4,490	... %	3,453	16.8 %	5.3 % Dim.
Ventilating heaters in use	2,705	13.3 %	3,444	16.7 %	3.4 % Gain
Indirect heating systems	809	4.2.%	1,004	4.. %	.02% Gain
No moisture supplied to air	7,..7	37.4 %	6,369	31.0.%	6.4 % Dim.
Windows, only means of ventilation	8,791	42.. %	7,..96	3..0 %	..3 % Dim.
Common drinking cup in use	3,147	15.3 %	1,849	9.0. %	6.3 % Dim.
Common towel in use	9,141	44.3 %	2,989	14.5 %	29. % Dim.
Surface or earth vault privies	...0	36.1 %	8,934	28.4 %	7.7 % Dim.
Modern flush closets in use	672	3.31%	764	3.72 %	.41% Gain

Fig. 7.—The results of inspection work in Pennsylvania as shown by percentages of diminution or gain are set forth in this table, the results in a typical year showing how slow a change is even as regards matters of physical environment.

serve to show some of the defects which have been reported, as well as the degree of success that has attended the remedial measures instituted. The reports from fourth class rural districts for two typical years have been selected for comparison.

It would appear at first sight that far greater improvement should be attained in a matter so comparatively simple as school environment. Experience, however, has taught us that even such a simple problem as unjacketed stoves is moderately complex. School funds are first available for teacher's salary, heat, and books; in many poor districts when these essentials have been procured the treasury is depleted. In other districts plans have been drawn up for new and modern structures and it seems unwise to force an expenditure for the correction of defects which will be of service for but one or two years and which will jeopardize the execution of plans for the new structure. But aside from such districts, there are many which are content to preserve the school houses of their forefathers unaltered, and nothing but the strong arm of the law will arouse them from their self-satisfied state.

LABOR BUREAU COUNCIL

The Fifth Session of the Executive Council of the International Labor Bureau was held October 5 in the Council's permanent quarters at Geneva, Switzerland, the Council consisting of twenty-two government representatives, six representatives of workers, and six of employers.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

A PROGRAM OF CHILD HYGIENE

WHATEVER may be the attitude of the medical profession and of public health workers toward other fields of public health endeavor, the concentration of attention on the problems of child welfare must meet universal approval. No one phase of child life can be isolated and treated as an entity. By the relation of the birth rate to the general mortality the vigor of a nation may be rated; and, likewise, the welfare and survival of those children are a safe index of the social status of a people. The birth rate of native American families has shown a steady and marked decrease. The same change takes place in the birth rate shown by immigrant families after the second or third generation, a change which causes no alarm if at the same time the social circumstances are modified so as to cause a parallel decline in infant mortality.

It has been pointed out that in medico-sociological history of the past fifty years the foremost position must be given to the steady decline of the birth rate in most civilized countries, and to the increased attention devoted to the welfare of infants and their mothers. Attempts at controlling infant mortality need to be on definitely public health lines. To the work of the American Child Hygiene Association must be accredited a highly effectual effort toward the coordination of all national agencies having definitely worked out programs for child welfare. The Report submitted to the Association by their director, Dr. Richard A. Bolt, at their Eleventh Annual Meeting, held in St. Louis, October 11-13, constitutes a valuable document showing the trend of recent months in this field, and the positive contribution of the American Child Hygiene Association toward the scientific investigation of child hygiene problems which makes for satisfactory methods of solution.

During the past year the Association has studied the work of similar organizations, the result of this inquiry being published as "A Digest of Programs of National Organizations Doing Child Welfare." Growing out of this work, and from suggestions received at the medical conference of the League of Red Cross Societies, at Cannes, the need developed for the formation of a national council for the purpose of coordinating child health activities. After a number of conferences with Dr. Livingstone Farrand, of the American Red Cross, Dr. Philip Van Ingen, of the Child Hygiene Association, Dr. L. Emmett Holt, of the National Child Labor Committee, Miss Sally Lucas Jean, and Miss Ella Phillipps Crandall, and Mr. Owen Lovejoy, an organization was finally effected.

Other fruitful channels of activity have been in the work of the Association in outlining the program for the Child Hygiene Section of the American Public Health Association and conferences with other national organizations looking toward closer coordination of work. There has been cooperation with government bureaus, and propaganda and educational work have no doubt reacted favorably in the action taken on the Child and Maternity Bill which will be taken up for action in the coming Congress. Field work is being developed; *Mother and Child*, the new publication, is being expanded. The attendance and personnel of the St. Louis Conference attest the serious purpose of these workers, and the papers presented represent the best thought and scientific procedure, not only in the study and prevention of infant mortality, but also in the development of a broad socio-medical program for the whole of infancy and childhood. The election of Herbert Hoover to the office of president assures the effectual continuation of the program outlined. S. P. M.

COLLEGE OF AMERICAN DENTISTS

To the end that proficiency in the profession may receive new encouragement and that research work may be expanded, the National Dental Association in its recent convention at Boston announced the organization of another society to be known as the College of American Dentists. It will bestow degrees upon men who do meritorious work in dentistry and will encourage postgraduate work. The college will have headquarters in Chicago and will operate through a large board of censors who, unknown to the community, will watch the progress and performances of practising dentists and students and report any specially meritorious work for recommendation for degrees or other action tending to elevate the profession. Its function will not be to teach, but it will afford a stimulus to research.

The officers elected are: John V. Conzett, M.D., of Dubuque, Iowa, president; H. E. Friesell, M.D., of Pittsburgh, Pa., vice-president; Arthur D. Black, M.D., of Chicago, secretary; and C. Kels, M.D., Chicago, treasurer. A board of trustees was elected, consisting of the president, vice-president, secretary, and Roscoe Volland, M.D., of Des Moines, Iowa; Thomas P. Hinman, M.D., of Atlanta, Ga.; H. J. Burkhart, M.D., of Rochester, N. Y.; and Clarence Grieves, M.D., of Baltimore, Md.

PRESENT DAY SOCIAL HYGIENE PROBLEMS*

By LEE ALEXANDER STONE, M.D., Surgeon (R), Regional Consultant, United States Public Health Service, Chicago, Ill.

THERE is such a close interrelation of all health problems that I beg the privilege of prefacing my remarks by a brief statement of the child hygiene activities of the United States Public Health Service, to emphasize the relationship of these activities to the venereal disease control activities of the Service. In briefly outlining this work, I wish it to serve as a means of emphasizing the importance of placing all administration of health matters under one central authority. Not only does this prevent duplication of effort, but it also accomplishes the best results with a minimum of expenditure. Any constituted health official who attempts to concentrate his activities on any particular sex, age, or race group, or on any particular limited geographical area under his jurisdiction without due consideration of related problems will fail most signally in correcting conditions injurious to the groups or districts in which he is particularly interested.

Coordinates With All Health Work

In the state of Missouri the Public Health Service is cooperating with the state Department of Health and a number of volunteer organizations, including the American Red Cross, the Missouri Association for the Control and Relief of Tuberculosis, the Extension Division of the State University, and other agencies, in bringing about better supervision of the health of expectant mothers, infants, children of pre-school and school age, and of children in industry. This work is peculiar in that it has resulted in bringing about a state wide sentiment in favor of placing this work on a self-paying local basis, and is even now resulting in improved birth registration and the provision of increased facilities for the care of mothers, infants, and children.

The great importance of this work as related to venereal disease control is shown particularly by the prenatal care activities. For example, in a recent report of routine Wassermann examinations of 1,840 children it was found that nearly 9 per cent were syphilitic and that in every case, with but one exception, this was of the congenital type, and not acquired. Furthermore, in an examination of fetal and placental tissues in the cases of more than seven hundred miscarriages and abortions which was made in the Johns Hopkins Hospital laboratories, approximately 25 per cent were found to be syphilitic. In addition to the children born dead and those who survive for a longer or shorter period, as in the case of the children just mentioned, an unknown number, which assuredly must be large, die shortly after birth as a result of syphilis. In addition to this must be considered the statistics which relate to blindness as a result of *ophthalmia neonatorum*. It is clear, therefore, that the child hygiene work of the Public Health Service is also venereal disease control work, because, if properly conducted, more and more mothers suffering from syphilis are discovered and put on appropriate treatment, and larger numbers of them suffering from gonorrhea are cured; in just such degree will better and better control of venereal diseases be attained.

Other child hygiene activities of the Service, as they relate to the nutrition and food problems of children, health supervision of children, care of children of preschool age, supervision of the health of children in industry, and the mental hygiene activities as they relate to the child, might be emphasized, but this cannot be done within the limits of time allotted for this discussion. All of this work is educational and corrective and results in improved stamina and resistance to infection, better knowledge of the principles of general and personal hygiene, better supervision of the health of mothers and children, improved facilities for the care and treatment of necessitous cases, detection and training of children exhibiting antisocial tendencies, and improved facilities for the care and training of the feeble-minded children who in later life are such potential sources of venereal disease infection.

At the time of America's entry into the war many unforeseen things presented themselves for settlement. Those in charge of military affairs faced the mobilizing of troops and the problem of handling great numbers of men who were to become part of the large army the United States expected to raise. In the past, soldiers, except when in action, were permitted certain privileges after their day's work was over that in many instances proved disastrous to their moral, physical, and mental well being. They were considered free-lances, and as such came into contact with many things which were demoralizing and vicious as well.

It was believed by many that a soldier could not measure up to the standards expected of him as a fighter unless he caroused, associated with prostitutes, and drank a little too much at times. All one has to do is to recall to mind the actions of the troops during the Spanish-American War, when "license" was the pass-word, and to remember how drunken soldiers took, in some instances, complete charge of segregated districts near their camps. The inmates of these districts combined to turn midnight revelries into orgies of the most awful depravity. Soldiers drank, lost complete control of themselves, threw aside caution, and yielded to lewd and lascivious practices that in sober moments they would have disdained as being beneath them. As a consequence of this license, the usual happened. Venereal diseases, with all of their attendant horrors, flourished.

Many a young man may trace the cause of his present disability to a type of licentious indulgence engaged in by him when he went as a soldier to the Mexican border in 1916. Prostitution flourished in El Paso and other small cities wherever soldiers were stationed. Apparently no attempt was made to stop it, and boys who left homes of purity were forced to witness depravity in its worst phases.

It is stated that when one expedition went into Mexico prostitutes were carried along and that when a permanent camp was finally located, a stockade entirely surrounded with barbed wire was built and stocked with these women. This stockade is said to have been located within seven hundred yards of the commanding general's headquarters. The women were kept for the use of the men of this expedition and a uniform charge of two dollars for the use of their bodies was made.

Very little is known about this pen for females, because

*An address delivered before the National Congress of Mothers and Parent-Teachers Associations, Madison, Wis., June 6, 1920.

of a rigid censorship that forbade any information coming out of Mexico relative to the actions of the Army there.

It seems a pity to be forced to open up out of the past that part of army life which was repugnant to hundreds of commanding officers, yet, because of the custom of turning soldiers loose to do as they pleased, absolutely no surveillance being placed over them after drill periods, officers hesitated or absolutely refused to notice the actions of their men, for fear of being considered meddlers or mollycoddles.

When Congress declared war against Germany, the men upon whose shoulders devolved the putting into action of the orders of the Senate and House of Representatives were puzzled. Were they to adhere to the old ideas so long in vogue or were they to blaze for themselves a new trail that might in all probability bring criticism on them from those who believed in license; should they establish a new order of things that would so conserve the manhood of the proposed army as to send it fit in every particular—morally, mentally, and physically—to win the great battles the leaders knew must be fought before victory could be won?

The latter course was chosen. Men known to have spent their lives in certain professions which had the welfare of the nation at heart were sent for and a great conference was held, with the result that the United States forged ahead of every other nation in Christendom so far as the looking after the physical welfare of her soldiery was concerned.

Cordons were thrown around every cantonment and post where soldiers were being prepared for duty overseas. Men in uniform were not permitted any alcoholic beverages, nor were saloon keepers, hotel proprietors, or even friends, allowed to serve or sell them, under penalty of a fine and imprisonment.

All houses of prostitution were closed in the region of camps, and the military police were instructed to arrest men seen associating with women suspected of belonging to the underworld.

Athletic sports were provided to divert the minds of the men in training. Theaters were built in all of the camps by the War Department. First class talent came to these houses of amusement and put on good shows. The Young Men's Christian Association, Knights of Columbus, and the Young Women's Christian Association provided, in the buildings they constructed, meeting places for the men where they could obtain stationery for their correspondence free, and also where they might witness good moving pictures at least twice weekly. These organizations are deserving of great credit. The Young Women's Christian Association should be mentioned specifically. This organization, composed entirely of women, provided means whereby enlisted men and officers might meet their female relatives, their lady friends, and sweethearts. The work they did made it possible for many a mother to see her boy, and for sweethearts to greet their soldier lovers. Many wives of the men also enjoyed the hospitality of these good women. Too much cannot be said in praise of the magnificent efforts they put forth to aid this country to win the war and of the service of the "Hostess House."

Schools were started wherein the enlisted man might become mentally efficient, thereby eliminating in a large measure idleness after drill periods were over. It was amazing how very little loafing was observable around cantonments that in some instances housed as many as 50,000 men.

All of the above agencies revolutionized antiquated methods of the past and drove to cover those who formerly had preached the doctrine of license. In the face of the elaborate scheme developed, as stated, something was lacking. It was discovered that the men were hopelessly ignorant as to the processes involving reproduction and the dangers attending if their reproductive organs were maltreated and not used as they should be to beget children after their marriage.

It fell to the author's lot to be called upon, along with four or five others, to address large bodies of men in camps on the more intimate things life had in store for them. It was his privilege to address approximately one million soldiers and to give them a type of instruction that should have begun in their babyhood. The ignorance of the men and their officers was in many instances pathetic. Many officers and men came up after the lectures were over to ask questions and also to ask the almost universal question, which was to this effect: "Why didn't my mother or my father explain to me the things I have heard today? If they had I should have been a better man."

One American general, who at one time in his life had been a physician, stated at the beginning of the war, before the entry of the United States, when he was urging "preparedness" from the public platform, that in the future wars must be fought by men clean in body and in mind. He further stated that unless mothers could receive a guarantee that the moral and physical welfare of their boys was to be looked after, they would not be willing to give them to their country. No mother wants to know that, when her son leaves her side to fight for his homeland, he and his associates in all probability will be drawn into the web of sensuality and lasciviousness. This general has always maintained that the existence of prostitutes around military camps is not necessary to the well being of the soldier. He has been ready at all times to defend his position and to protect his men from the pernicious influence of the old school. Camp Funston, where he commanded two divisions and prepared them for overseas duty, boasted of the fact that the young men camped there were safer than if they had been in their homes. Practically every cantonment was a better place for the soldier than his home city.

Mock Modesty the Curse of the Nation

No wiser thing was ever done by any government than that which the United States attempted when it began instructing the young men in its army to respect their bodies and view them as being temples erected in the image of God, and not to be defiled. Four million men were benefited by the instruction they received, and many a boy was saved from errors he would have committed through ignorance. The majority of those who slip into what society calls sin do so because society is to blame in having permitted the iniquity of ignorance to exist, and in having been swayed by the teacher of a doctrine that refused to recognize the sacredness of the procreative act. Mock modesty is the curse of the Nation. Mock modesty is a deadly sin. Mock modesty is a disease that has infected with its prurience and hypocrisy more men and women and mothers and fathers than has any other ailment to be found in the world today. The mock modest person is usually the one who taboos as being nasty anything that pertains to the functions of birth. This same mock modest individual will blush and hide behind a fan or behind the hand at the mention of the natural functions of the body, always, however, making it possible to look over the one and through the other.

It is the proud boast of those who know that, as a result of the things taught in the army to its soldiery,

never before in history has there been such an aggregation of men who were morally and physically so fit to go into battle. It can be said without fear of contradiction that the United States Army was the cleanest army in all the world, and that there never had been such a clean lot of men in uniform before.

Of the four million men under arms in the United States and abroad, there were only 227,000 cases of venereal disease up to February, 1919. Five-sixths of all of the gonorrhea and syphilis in the army was—to the shame of the communities from whence the soldiers came—contracted before the men entered the service and was brought into it by them. Approximately thirty-eight thousand cases were contracted after the troops went into training, and this number is very small indeed when it is considered that in the French army alone, according to Pautrier's estimate, there were 200,000 cases of syphilis. At one time in the Austrian army, according to Hecht, there was the equal of sixty entire divisions out of action because of venereal diseases. The English, Belgian, and Italian armies were infested with these agencies that are rightly called racial poisons.

If it was known, no man belonging to the United States forces was allowed to go to the front line if he was found to be infected. Inspections were held regularly, and any man discovered to be diseased was locked up in a detention hospital and there kept until such time might arrive when he would no longer be a menace to his fellows. A man with venereal disease among the American forces was considered a slacker. His pay was taken from him and he was not allowed to enjoy any of the privileges his comrades were enjoying. He went before a summary court-martial and was sentenced.

Every true American should feel pride surge in his bosom when he considers the actions of the boys who did their bit in the World War. Men, free from the blight of the most terrible of all plagues, faced the Hun, drove him back across No-Man's-Land, and whipped him at every point. When the final crash came, Germany could not stand up against men whose bodies had never been burnt by the fires of venereal disease.

Thousands of the bodies of these men are still somewhere on the fields of France; the souls that once inhabited them have "gone West." The souls of these immortal men, who in the heroic hour proved themselves men in the greatest sense, are crying aloud and asking, now the war is over, that America redeem herself again and throw around her civil population the same protection she threw around her fighting men.

Lighten the Dark Places

There is a crying need for a type of publicity for gonorrhea and syphilis in civil life that will bring them into the light of day. The "hidden menace" in society is venereal disease, and just so long as racial poisons are allowed to remain in Stygian darkness and, like the thief in the night, to dart out and steal that which is most to be desired by man—his health—and then dart back again where they cannot be seen and remain unmolested until ready to strike again, men and women will go down and the welfare of future generations will be jeopardized.

In the United States 770,000 young men reach the age of twenty-one years every year. It is conservatively estimated that of this number 60 per cent, or more than 450,000, will contract either gonorrhea or syphilis, or it may be both, before they reach the age of thirty. Is not a statement of this nature enough to rouse thinking men and women to action? The innoculation of 450,000 young men with the virus of syphilis or gonorrhea means that in all probability an equal number of young women will become infected. All of these young men contemplate marriage, and in the nuptial embrace, unless their treatment has been very thorough, they will almost surely infect their wives. The infecting of the wife, particularly with syphilis, means infected offspring, while gonorrhea may blind the baby as its head emerges from the soft parts of the mother. A guarantee of health must be given the child of the future.

Many claim that a young man should sow a crop of wild oats, "paint the town red," and associate with prostitutes before he marries; that unless he does, he is not rightly entitled to the cognomen man. If the average man who teaches such a doctrine could only reckon the consequences of the sowing of a crop of wild oats, he would hesitate before advising their sowing. The sower should be made to realize that whatever he sows must some day be reaped,—no seed falls to the ground except that a harvest of some kind is reaped from it. The harvest of the crop of wild oats is usually reaped with the flail of pain, agony, and disaster, not alone to the sower but to those to whom he should have brought purity. The wife and her offspring are most usually the ones to reap the full harvest. From 75 per cent to 95 per cent of all diseases in the female pelvis are due to gonorrhea. Thus does the wife reap; blindness in the newborn is in 80 per cent of all cases produced by gonorrhea; the child truly harvests the crop of its father's wild oats that will last it throughout its life; it must go through its existence in darkness, a living rebuke to him who should have gone to his mother free from taint.

Gonorrhea produces an arthritis, commonly called gonorrheal rheumatism, that is very painful. This condition frequently develops into a heart trouble. Thousands of men are sterile because of gonorrhea, and blame their wives for not giving them babies when they themselves can trace the cause to a time when they chose to violate their own chastity because they had been told the age old lie that continence is harmful. Just a word by way of diversion: Continence is possible. It is just as healthful for a man to refrain from sex indulgence until he marries as it is for a woman. Men demand chastity of the women they marry and declare they would not wed those who are unclean morally. They refuse to see how inconsistent they are, but insist that sexual intercourse is necessary to their well being and that unless they indulge, their health will be impaired.

No man should demand more of a woman than he is willing to give in return. His failure to give proves him a weakling and the woman the stronger of the two. Sexual intercourse indulged in by single men is absolutely not necessary to keep up manly vigor. Men have been known to abstain for years from indulging in sexual relationships and still maintain their virility. Continence has been proved healthful by scientists.

(Continued)

Nine of every ten children are born healthy. Twenty years later 20 per cent of them are dead; another 20 per cent are so defective as to be incapable of military service; of the remaining 60 per cent, one-half bear the visible marks of physical defects and two-thirds are so mentally deficient that they earn less than $15 a week. Surely someone is responsible for this postnatal deterioration. . . . Why save the child if a moral docility and physical decrepitude is induced which adds to world misery and shortens life? Should we count our progress by the number of babies saved or by the increased vigor and longevity of adults?—*Patten.*

THE STATE AND FUTURE OF MEDICAL PRACTICE*

By SIR GEORGE NEWMAN, K.C.B., M.D. Edinburgh, F.R.C.P. London

FROM the earliest times the doctor has served the state, but in this country the direct interrelationship is not yet a century old. In 1830 the only direct medical interest of the state, as represented in the Government of the day, was quarantine and vaccination. But in 1831 the Government became anxious about the spread of cholera, then moving towards us from Russia, and an advisory board of health was formed, cholera dispensaries established, and inquiries instituted. One of the results was a measure of defense against cholera, but, far more important, interest was awakened in the insanitary conditions amid which the mass of the people lived—an interest which was confirmed by the inquiries of the Poor-Law Commissioners appointed under the Poor-Law Amendment Act of 1834. No statute before that of 1834 had definitely provided for the state medical treatment of the pauper, though from 1536 the sick poor had been differentiated from the able bodied. The famous Poor-Law of Queen Elizabeth in 1601 had required the "necessary relief" of the disabled pauper, and under that enactment a wide and rather indiscriminate practice of medical treatment had in fact arisen. Thus it came about that between 1834 and 1838 the Poor-Law medical service emerged as the forerunner of the public health service; in 1839 Farr began his work on medical statistics; in 1847 the first medical officer of health was appointed; and in 1855 a central medical department was established in Whitehall—first under the Board of Health (1855-58), then under the Privy Council (1858-71), then under the Local Government Board (1871-1919), and, lastly, under the Ministry of Health (1919). These four historical steps in development from the Poor-Law origin laid the foundation of the present position of state medicine for the civil community—the Poor-Law medical service under 636 Poor-Law unions and upwards of four thousand medical men, the public health service under 1,800 sanitary authorities and 318 local education authorities, with a composite staff of another 3,000 medical officers, the Registrar-General's Department, and the Ministry of Health.

The State and the Doctor

Alongside this entrance of medical men into direct state service there was constantly proceeding a further imposition of statutory duties upon the medical practitioner. Apart from the fact that he may be called upon to undertake official duties in the public service, he is liable under statute in the following respects: (1) He must certify births and deaths (Births and Deaths Registration Act, 1874), and notify all births within thirty-six hours (Notification of Births Acts, 1907-1915); he must notify cases of infectious disease (Infectious Notification Acts, 1889 and 1899, and special notification regulations as issued), of industrial poisoning (Factory and Workshop Act, 1901), and of verminous children (Children Act, 1908). He must also be ready to vaccinate (Vaccination Acts, 1871-1907) and to certify the removal of infectious cases to hospitals (Public Health Act, 1875). (2) He may be called upon to inspect and certify for house disinfection (Public Health Act, 1875, and Infectious Disease Prevention Act, 1890), and be prepared to issue certificates for the removal and burial of dead bodies (Ibid.). (3) He may be required to inspect and condemn in regard to nuisances and insanitary house property (Public Health Act, 1875, or Amendment Act, 1907), or inquire into unhealthy or insanitary areas (Housing of the Working Classes Act, 1890). (4) He must know something of the ill effect upon health of dangerous or offensive trades (Public Health Act, 1875), and of unsound food (Public Health [Unsound Food] Regulations, 1908). (5) He must be competent to diagnose all forms of mental disease (Mental Deficiency Act, 1913). (6) He must be available to respond to the requirements of the local sanitary authority for the provision of medical assistance and treatment for the poorer inhabitants of the district in which he lives (Public Health Act, 1875, s. 133). (7) He is liable for a series of duties in regard to workmen's compensation (Workmen's Compensation Act, 1906, s. 8), superannuation, and pension claims (Ministry of Pensions Act). (8) He may be called in by a midwife in cases of emergency (Midwives Act, 1918, s. 25). (9) The local education authority may avail themselves of his services in connection with the treatment of children and young persons (Education Act, 1918, s. 25).

Lastly, the state has in recent years organized in behalf of the community certain branches of ordinary and special clinical work. The National Insurance Act of 1911 brought twelve million insured persons into medical benefit, at present provided by twelve thousand doctors and ten thousand chemists; systematic provision has been initiated for tuberculosis, venereal disease, and maternity and infant welfare; the organized treatment of early mental disease, ophthalmology, and tropical disease; and the large questions of orthopedics, and the treatment of industrial diseases are now under discussion; and an ever widening field of public dispensaries, clinics, and hospitals has opened before the profession.

Doctor Bears New Relation to State

These are profound changes. They divert, in a handful of years, the whole course of applied medicine from its century old pathway. They do not abolish the private medical practitioner, but they bring him into different relation to the state. Their present and future relation must be confirmed and made good on both sides; for, on the one hand, the profession is conscious of new obligations, both those imposed by law and those imposed by a sense of what is demanded by the civilization in which they live; and, on the other hand, the state is conscious, as never before, of the community's need of the profession, and the value of the profession's help if sought on the right terms and given in the right spirit. The greatest need on both sides is understanding. Value is the result of the application of mind to matter. The new problem is for the state and profession to come to a realization of the principles which should govern their interrelation. It is an association peculiarly difficult. For historical reasons the state—which means for the present purposes all authorities, local as well as central, concerned with health—has seen *prima facie* in the profession a body insistent upon the privacy and individuality of its work, the sanctity of its traditions, the freedom of its engagements. Correlatively the profession has seen in the state an organization apparently devoted to the infringement of these traditions and incapable of

*Reprint authorized by the editor of the Lancet, London. Published in the Lancet under date of July 17, 1920.

putting anything worthy in their place. It has been suspicious and mistrustful of what it considers to be unnecessary intervention. It has feared the imposition of some cast iron system, some form of so-called "nationalization," the institution of a whole time civil service, which in practice make the practitioner of medicine servile, dependent, and fettered.

What can improve this relation? The answer to this question seems to be—a larger measure of understanding by the doctor of the business of central and local government as representing the whole community, and by the state and its officers and representatives, high and low, of the history, development, and genius of professional character. The doctor should know something of the respective functions of Parliament, of the Cabinet, of the Treasury, of the dozen departments dealing with health problems as subordinate to their main functions, of the Ministry of Health (medical and lay), and its Medical Consultative Council. Further, he should know the meaning of the English system of local government; how it has evolved; why the country is subdivided into shires, boroughs, urban and rural districts and parishes, and what the main purposes are of the respective bodies providing for health, pensions Poor-Law, education, and insurance. For it is only by such knowledge, inspired by the historical spirit, that the doctor can obtain a grasp of the machinery by which and through which he can render his communal service to the state. He will discover, incidentally, the working of some of the great principles of representative government and the guarantee of its freedom.[1] The layman, what Anthony Trollope, following ancient custom, called "the clerk," besides specialized knowledge of the law and practice with which he is primarily concerned, should learn as much as he can of professional tradition and sentiment, of the scope and opportunity of voluntary work—from the great hospitals downwards—which touches the profession, of professional organizations, and of their history and relation to each other.

Such knowledge on both sides has a direct bearing on the effective working out of the extended relations between the profession and the state which it is now recognized are inevitable. It would enable doctors to understand those necessary and, at first sight, rather remarkable limitations of government action, which at present he deems to be merely stupidity. For instance, in official work regard must be paid to uniformity, to a "national minimum," to what is practicable rather than what is desirable, to the restrictions of the law, and to public economy. The layman, in his turn, will learn why doctors are jealous of the private practice, of the system of hospital appointments, of the restrictions of whole time work under public authorities, of the whole personal honor, integrity, and etiquette. These matters are not merely expressions of idiosyncrasy, prejudice, or narrowness of mind. They have behind them a long history, sound reason, and something of a philosophy. Some of them may be vestigial remains of a dead past; others have come to us, living, virile, and purposive, across two thousand five hundred years from the days of Hippocrates.

The general effect of this suggested change of outlook would be that the doctor became more political in the true Greek sense, and not with any partisan or meretricious meaning, but rather in the sense in which man was described as a political being, conscious and considerate of the community in which he lives; and Whitehall and the local authorities would realize how far short they are of full understanding of the profession with whom they must work, and of its growing cohesiveness, its quest of truth, and its undying spirit of "love of humanity, associated with love of craft."

Partly by way of illustration of the application of these general principles, and partly by way of demonstration of their necessity, I propose to mention briefly the five outstanding problems which now face the medical profession in its relation to the state. It will be understood that my purpose is to open a discussion and not close one, and that I am speaking wholly in an unofficial capacity.

The Unit of Health Government

The present system of local government in England is like an Egyptian palimpsest, composed in several lays of design laying one upon the other. At the bottom there are the Poor-Law unions; next above them and three times more numerous are the local sanitary authorities; superimposed upon which comes the local education authorities (318); then the Insurance Committees, numbering 145; and at the top the latest addition, the Local War Pensions Committees. Thus the whole country is mapped out five times over, but the charting has been done by different hands, at different times, and for different purposes. Hence arises duplication, overlapping, and confusion. There is confusion in areas and authorities, but there is no less confusion in the family. There are five local authorities concerned with maternity and infancy; three with children of school age; six authorities deal with persons of unsound mind or mental deficiency; four authorities are concerned with "sick persons"; three with the aged poor; and five with the able bodied poor. It is all anomalous, extravagant and redundant, with a result which is ineffective and wasteful.

What we seem to need in the abstract is, first a single unit of health government with necessary subcommittees for particular purposes. The principles which should guide us in devising such local authority are: (1) the concentration, as far as practicable, in one authority in each area, of the responsibility for all administration of health services from local rates, with or without exchequer grant in aid; (2) the absorption of the work of the Poor-Law and insurance in a public health service and the use by that service for the whole community of Poor-Law medical institutions; and (3) the unification in appropriate committees of the local authority of all public medical provision for the sick and infirm of all ages. Clearly, there would be advantage in thus having one authority for all health purposes—for a Poor-Law medical service, sanitation, education, insurance, and pensions—and towards unification of this nature many are looking. But the question is large and complex, and there are many considerations to which regard must be paid in prescribing a unit of sanitary government, including its history, size, population, urbanization, character of its industry and society, intercommunication, rating, relation to local and central government, and so forth. If a large local unit be contemplated, it would be necessary to provide for the encouragement of a consciousness of community of interest and aim in the smaller contributory or constituent divisions, with appropriate delegation of powers or functions in accordance with services to be rendered. The large autonomous body might in that way delegate some of the actual detail work to the more local bodies. If, on the other hand, a small local unit be contemplated, many analogous questions would arise.

1. I may perhaps venture to commend a perusal of Lawrence Lowell's Government of England (2 vols.) or the little volume on The English Constitution by Walter Bagehot (in Nelson's Series), and the three admirable pamphlets on The Business of Government Ministry of Reconstruction, H.M.S.O., No. 38, 2d.)

All I desire to do here is to name the general principle of unification as one to which attention must be given.

There is a second, somewhat similar, common-sense requirement—namely, *uniformity of administration*—in all comparable areas. All through the country and in all departments of state medicine there is need for introduction of accepted standards and a larger measure of equalization and uniformity of central and local action. There remains a third principle which the profession must not allow itself to forget—namely, that the local unit of health government must be *representative* of the will of the people as a whole. It cannot be wholly medical in personnel or in purpose. It must be comprehensive and disinterested. "Our trade our politics" is never sound statecraft.

Now, in devising this reform the medical profession must, in the interest of the state not less than the profession, take their share, exchanging with the layman their views on many points—the nature of the authority, its membership, the question of coöption of experts, finance, medical participation, the respective functioning of the different local committees, the use and adaptation of existing institutions, and their economical arrangement, and the place and character of the domiciliary medical services.

Extension of Medical Provision

Here again is a pressing problem calling partly for unification and simplification and partly for systematic organization. At present there are inadequacy, unequal provision, and piecemeal effort. We shall never get an ordered scheme in that way. We need a national policy—a program, so to speak—dealing seriatim with the medical problems of maternity, infancy, children, adolescence, adult life, and old age; with environment of home and workshop; with the prevention and cure of non-infectious diseases as well as infectious; and with the education of the public in hygiene. Here to deal with infancy, and there to neglect it; here to have a "stunt" in venereal disease, and there to provide nothing; here to organize a public medical service, and there to leave all things to chance—is not the way either of science or common sense. Then we require, in much greater degree, to bring together in proper relation the provision of medical treatment in the home, at the clinic, in the hospital, and in the convalescent institution, not for the pauper class only, but for the whole of society.

All this means that the profession should help in the consideration of these matters, for, while they constitute only a section of the community of ratepayers, and therefore have only a share in the decision, their knowledge and experience, and the fact that they must in large degree undertake the actual working of any scheme, entitles them to a voice in the form of the scheme. For what sections of the populace should provision be made? For what forms of treatment? Under what principles as to availability, adequacy, and payment? What is to be the part of lot of the private practitioner in the undertaking. And, lastly, what does the medical profession say to the concurrent operation of three incomplete and independent public medical services (Poor-Law, Insurance, and Public Health), and is it possible to unify their divergent claims. And, if so, what should be the basis of payment and its relative burden on the state, on the local authority, and on the income of the patient?

Future of the Hospital System

A third example of problems awaiting us is that of hospital position. The number of hospitals in England and Wales in 1915 was reported to be as follows:

	No.	Beds
General hospitals	594	31,329
Special hospitals	222	13,654
Fever hospitals	755	31,149
Smallpox hospitals	363	7,972
Poor-Law infirmaries	700	94,000

This gives us approximately two thousand six hundred hospitals with 178,000 beds, of which 700 institutions and 94,000 beds belong to the Poor-Law. In regard to this Poor-Law accommodation three things must be said here: (1) It is provided out of the poor rate and for persons in receipt of poor relief. (2) Of the 636 Poor-Law unions only fifty-four possess separate infirmaries (of which twenty-six are in metropolitan unions); 331 unions have "sick" beds in the curtilage of the workhouse, and the remaining 251 unions have no special in-patient accommodation. (3) A large proportion, perhaps even one-third, of the in-patient accommodation in all Poor-Law institutions are empty. These points are important when considering the practicability of transfer of Poor-Law beds to the general community. No doubt from the medical point of view, the community stands in urgent need of more hospital accommodation—we have overcrowded hospitals and long waiting lists on the one hand, and on the other inability to build new hospitals, and yet many empty Poor-Law beds. But the solution is not as simple as it looks, and the situation is complicated by many other hospital problems too often overlooked. Let me name some of them.

Is the principle of voluntary financial support to continue in our hospital system, or is the profession in favor of Government aid and some measure of Government control. Ought the hospital accommodation of the community to be allocated by the state in respect of area or type of clinical work undertaken, or ought it to continue to be provided in haphazard fashion? Is the medical and surgical staff to remain honorary? Is it to be a special professional class, or composed in part, at least, of general practitioners? What is to be the relation of hospitals to each other and to contributory clinics, and to the insurance system? How are we to bring about the substantial reform of the out-patient departments which is so greatly needed? Ought we to make provision for paying patients; and, if so, on what basis? Can we fairly provide for the insured and the pauper while neglecting to provide for the remaining majority? And, lastly, what can be done to reorganize after-care and the proper convalescent treatment of the patient? These are some typical issues which arise, and they are but illustrations. For their right answers they require medical as well as lay judgment and experience.

Medical Education Inadequate

A fourth subject, and perhaps the most important of all, is an adequate method of medical education which shall equip the undergraduate and the practitioner. The new services of the doctor to the state call for a reconsideration of the whole business or education and equipment. A different kind of doctor is needed in these new times. It is clear he must have no less of the learning and skill of former days, whilst he must also be furnished with an improved training in new subjects, in preventive medicine, and in the political science of communal responsibility. We are all convinced that the pivot of the profession is the general practitioner. If he is properly equipped the future is safe. Some specialization of practice there must be, for no man, be his powers what they may, can be master of all branches of medicine. Never-

theless, it is incumbent upon us to recognize that such diseases as tuberculosis and venereal and heart disease will never come under control until and unless the general practitioner is in a position to deal with them. Much of the special provision which has been made by the state in recent years has been necessary, first, because of the need for institutional accommodation to effect cure, and, secondly, because adequate treatment by the private practitioner was unavailable.

In my view, the state should never take out of the hands of the general practitioner, whether in contractual practice or otherwise, the patient whom he is willing and competent to handle on reasonable terms. The difficulty has been that the practitioner has not been in a position to render the medical service required by the state. It is evident that the solution is dependent partly upon reform in the medical schools—a reform which, happily, is proceeding rapidly—and partly upon adequate arrangements for graduate education for the practitioner, and, may I add, willingness on his part to avail himself of the facilities which are provided. There is much remaining to be done in both directions, but before substantial progress can be achieved there is first considerable apathy to be overcome and a fuller apprehension of the needs of the situation; and, secondly, the further education of the practitioner must include an adequate professoriate, hospital, and laboratory accommodation, and proper organization.

The Advancement of Humanism

As this section is concerned with "medical sociology," I venture to suggest one other sphere in which the medical man of this new age may put in his oar. It is not only an intellectual or medical advance of which our country stands in need. Closely akin to it there is a social need. Men are great in proportion as they absorb the best life of the world in which they live—its ideas, knowledge, hope, fears, aspiration—and quicken these anew in the minds of other men. As Sophocles said:

> Much is there passing strange,
> Nothing surpassing mankind.

No medical man who is in a right sense a man of the world can have failed to ponder often on the near relationship which obtains between the practice of medicine and the social life of the people. It has often been said our patients are not "cases" but men, women, and children, each with a separate personality, environment, heredity, and variation, with individual habits, training, temperament, and psychology. We cannot be wise healers of the patient of the community without a large sympathy and a liberal humanism—that fuller humanity with which the Oxford reformers inspired the Renaissance.

We are the witnesses of a strange and rapid transition in the life of the people as a whole, an enlarging franchise and new social complexes. Higher wages, shorter hours of work, increased leisure, high prices, and democratic aspirations are not remote from the national health and well being. The doctor must be the missionary of hygiene—the chief educator of the people in ways of health. In being that, he cannot escape his share of responsibility in the study and handling of many of the medicosociological questions which surround us—education, sobriety, cleanness of living, the prevalence of venereal disease, prostitution, the penal laws, the causes of certain crimes, the integrity of family life—all such questions concern us, and to fulfill our vows we must be concerned with them. The cultivation of international science, cooperation, and amity should also, I think, be added. It is essential that we should remember that whilst these issues belong to the warp and woof of medical polity, the decisive factor is not medical, and movements in favor of their determination on medical grounds only are doomed to failure. Let me remind you of a famous passage in Huxley's lecture at Oxford in 1893 on "Evolution and Ethics." He had been speaking of the cosmic process of Nature and he said:

> Social progress means a checking of the cosmic process at every step and the substitution for it of another, which may be called the ethical process, the end of which is not the survival of those who may happen to be fittest in respect of the whole of the conditions which exist, but of those who are ethically the best. The practice of that which is ethically best involves a course of conduct which in all respects is opposed to that which leads to success in the cosmic struggle for existence. In place of ruthless self-assertion it demands self-restraint; in place of thrusting aside or treading down all competitors it requires that the individual shall not merely respect but shall help his fellows; its influence is directed not so much to the survival of the fittest as to the fitting of as many as possible to survive. It repudiates the gladitorial theory of existence. It demands that each man who enters into the enjoyment of the advantages of a polity shall be mindful of his debt to those who have laboriously constructed it; and shall take heed that no act of his weakens the fabric in which he has been permitted to live.

These words are even more timely today than they were when they were spoken. He added: "Most men are agreed that the proportion of good and evil in life may be very sensibly affected by human action. . . . So far as we possess a power of bettering things it is our paramount duty to use it and to train all our intellect and energy to this supreme service of our kind."

The claims of the state on the profession have greatly increased owing to the advance in medicine and its manifold applications. A new and closer relationship between them is inevitable. It can be profitable in the public interest only by good understanding. There is something due from each to the other. The profession is responsible for its own contribution—a contribution which consists partly in a correct diagnosis of its own disabilities and the conflicting and prejudicial tendencies within its own body, partly in a fuller understanding of the needs of the state, and partly in readiness to make itself thoroughly well equipped and competent to render the remarkable public service which in this generation has fallen to its lot.

ABUSE OF DISPENSARIES

Last year, forty-six hospitals in New York City, not maintained by the city, reported that they provided 600,000 persons with free treatment, for a total of 1,203,728 treatments, for which neither the beneficiary nor the city paid. It has been estimated that during the year 1919 four million free treatments were given in the dispensaries of New York.

In view of Section 296, Chapter 55, of the Consolidated Laws, which says, "Any person who obtains medical or surgical treatment on false representation from any dispensary licensed under the provisions of this Act, shall be guilty of a misdemeanor, and on conviction thereof, etc.," the question is asked whether the giving of false home address by such persons is not a misdemeanor under the section. Recently a case of smallpox was found in a well known dispensary and, when those who had been exposed had been followed up at the addresses given as their homes, about two thirds could not be found.

The tragedy of all great cities is the tragedy of the child-life of the slums.—Robert W. Mackenna in "The Adventure of Life."

A STUDY OF DISPENSARY PATIENTS*

A Report by the Public Health Committee of the New York Academy of Medicine

WITH a view of obtaining more accurately than was feasible in the community survey the information about the types of patients using the dispensaries, their economic and social conditions, and the motives prompting them to resort to ambulatory treatment, 1,968 persons were interviewed at the dispensaries as they passed the registrar's desk or while they were sitting in the waiting rooms. These dispensary patients were interviewed at thirty-seven institutions. Agents of the committee spent from two to three days in each institution. Patients were selected at random from among these who had long waiting periods, so as not to interfere with the routine of the dispensary work. In this way, from forty to sixty patients were interviewed at each dispensary. At two institutions, the Babies' Hospital Dispensary and Lebanon Hospital Dispensary, it was not necessary to follow this procedure, because the registrars of these institutions obtain a great deal of this information as a routine procedure. Although their information did not cover all the points called for in our study, it seemed more desirable to utilize the available data than to submit the patients to a new inquiry along similar lines. Among those interrogated there were 454 men, 876 women, and 638 children under the age of 16. In most of the children's cases it was either the mother or the father who was questioned, and the information gained pertained to the family and not to the child alone. One-third of the patients were visited in their homes for the purpose of observing their home conditions and of checking as far as possible the statements given at the dispensary, as well as to ascertain the extent to which false addresses were given. The questions asked were those usually found on the "representation card," except that it was elaborated considerably in certain respects to obtain a clearer idea of the social and racial status of the patients and, also, of their ability to pay a private physician. On the form shown in Chart I was recorded the information gained. This will indicate the nature of the data which form the basis of this report.

*The fifth of a series of articles on dispensary service prepared for the pages of MODERN MEDICINE.

Age, Sex and Nationality

Of the total number of 1,968 patients, 24 per cent were American born; 12 per cent Italian; 31 per cent Hebrew; 8.5 per cent Irish; 4.5 per cent Slav; 5.7 per cent German; 5.8 per cent Negro; and 8.5 per cent miscellaneous, under which heading were grouped those belonging to various national or racial groups not previously indicated.

Of the total number of 1,968 patients, 40 per cent were between the ages of 16 and 36; 27.5 per cent were over 36; and 32.5 per cent were children under 16. Of the 454 men, a little over 50 per cent were among the age group under 36. Among the 876 women, 63 per cent were under 36, and 37 per cent were over 36. The age distribution of the patients by nationalities given below shows that the largest number of children cases were among the Italians, Hebrews, Irish, and Slavs, and the lowest among the native born. The variations between the various nationalities are not very pronounced in this respect. The largest percentage among young women was among the negro group. It was fairly high in the native-born group, and lowest among the Irish. Among the women over 36, the highest proportions were among Irish, Germans, and Hebrews. The least proportion of young men was found among the Irish and Germans, and the least proportions of men over 36 were in the miscellaneous group, the Slavs and the negroes, and the highest among the Irish and the Germans (Table I).

Nationality	Men 16 to 36		Men 36 plus		Women 16 to 36		Women 36 plus		Children under 16		Total	
	No.	Pct.	No.	Pct.	No.	Pct.	No.	Pct.	No.	Pct.	No.	Pct.
U. S. A.	69	14.4	49	10.2	178	37.2	69	14.4	114	23.8	479	24.
Italian	33	14.3	33	14.3	48	20.7	26	10.7	92	40.	231	12.
Hebrew	66	10.6	65	10.6	146	23.9	110	18.	226	36.8	611	31.
Irish	9	5.6	27	16.5	30	18.	42	26.	57	34.	166	8.5
Slav	12	13.7	8	9.2	26	28.6	13	16.	29	33.6	87	4.5
German	7	6.2	16	14.1	22	19.1	29	25.4	40	35.2	114	5.7
Negro	14	12.	11	9.4	49	41.9	11	9.4	32	27.3	117	6.8
Miscellaneous	26	15.	11	7.	53	32.	26	16.	49	30.	164	8.6
TOTAL	234	12.	260	11.	561	28.	326	16.6	638	32.6	1968	100.

An analysis of the proportions of men, women, and children among the several groups shows that the distribution of men was pretty nearly equal among the several races except that it was a little higher among the Italians and native born than in other groups. The proportions of women differ more than those of the men, being 51.3 per cent among the negro patients, 51.8 per cent among the native born, and only 31.4 per cent among the Italians.

Occupation and Financial Status

Of the 1,330 adult patients, 18.5 per cent were male family bread winners; 31.9 per cent were gainfully employed, but had no dependents; 47.6 per cent were housewives and mothers; and 2 per cent were dependent adults.

For 629 of the 1,330 adult patients we were able to obtain the occupation in which they were engaged. The distribution of the several trades is presented in Table II and, according to the classification, 11.8 per cent of the gainfully employed patients were in clerical work, 21.8 per cent in personal or domestic service, 6.3 per cent in the building trades, 13 per cent in the clothing trades, 9.4 per cent in transportation—including drivers and chauffeurs—4.6 per cent in sales work, 2.1 per cent in metal work, 13.5 per cent manufacturings of various kinds, 4.8 per cent were firemen or electricians or machinists, 5.2 per cent unskilled laborers, 2.2 per cent engaged in printing and bookbinding, 1.6 per cent were food handlers, 0.8 per cent were municipal employees, and 2.9 per cent were in a large number of miscellaneous occupations. The last group includes telephone operators, photographers, teachers, theatrical workers, soldiers and sailors, and one dentist (Table II).

Figuring the *per capita* weekly incomes as we did in the community survey described in another section of this report, we found (Table III) that 13.1 per cent of the families had an income of less than $4.50 *per capita* per week; 22.9 per cent had an income from $4.51 to $6.50; 19.6 per cent an income from $6.51 to $8.50; 11.2 per cent an income from $8.51 to $10.50. The remaining 255 families, or 12.9 per cent of the total from whom this information was obtained, had a larger income than $10.50 *per capita* per week. On the basis of budgetary studies made by the Bureau of Statistics of the Federal Department of Labor and of computations made by the Charity Organization Society of New York, an income of $8.50 *per capita* per week would provide the minimum

of living standard described in the study of Chapin for a family of man, woman, and three children. The indispensable income in 1907, when the Chapin study was made, was $900 a year in New York, and now it is $1,550. According to these family budget standards, the major portion of the dispensary patients included in the present study were below the line of the minimum normal standard of living. It must be remembered that the figures ascertained represent the income of the family if disease had not caused a considerable degree of unemployment directly or indirectly.

Excluding children, we found that 43 per cent were unemployed at the time when they were interviewed. Table IV gives the distribution of unemployment among

Note: This excludes 551 children and 289 others for whom this information was not obtained. These patients comprise 40 free babies and 50 from Lebanon Hospitals, at which institutions records were copied, and the patients from the clinics of the Manhattan Maternity, Lying-In, Sloane and Women's Hospitals, the majority of whom applied for prenatal or pediatric care.

the adult patients by nationality and by the extent of their disability.

Of those who were unemployed, 20.2 per cent had been unemployed for less than eight days at the time they were interviewed in the clinic; 18.3 per cent had been unemployed between eight days and a month; 26 per cent had been unemployed between one month and six months; and 18 per cent had been unemployed for more than six months. The largest relative amount of unemployment was, of course, among those who had been completely incapacitated, none of whom had been working. Of those who suffered intermittent disability, that is, those who had some chronic malady which incapacitated them from time to time, 52 per cent were out of work; 42 per cent of those who had partial incapacity were not working, and 21.4 per cent of those who suffered no incapacity were out of work. This large amount of unemployment, due to illness either directly or indirectly, rendered the financial status of most of the families rather precarious. This was borne out by the observations and inquiries made at the homes of 632 of the patients who were visited in their homes. Of these 632, only 545, or 86 per cent, were found to be living at the address given. The others evidently gave false addresses. In view of the fact that care was taken to obtain the address as accurately as possible, and also in view of the fact that the patients were visited a short time after the interview at the dispensary and therefore could not have moved from the places given as their abode, it may safely be assumed that 13 per cent of them gave wrong addresses, either deliberately or because of ignorance. Incidentally, it may be of interest to state that among the derelicts in this respect, the Hebrews were most numerous, 19.8 per cent of them not being found at the address given to the agent. They were followed by the Slavs, 16.6 per cent, and the Negroes, 14.2 per cent. The smallest amount of misinformation was found among the Italians and the Irish.

Of the 545 patients visited, 95.4 per cent were, in the judgment of the investigators, truthful with regard to the statement of their economic and family conditions. The Negroes were found to be the least truthful; in only 83.3 per cent of their cases was the story confirmed. The Slavs were just a bit better, and the remaining groups were about on the same level.

Dispensary Abuse

On the basis of the observations made and the data obtained, a classification was made of the patients with regard to whether or not they were justified in using the dispensary. This is, of course, a difficult task and does not lend itself to any precise ascertainment. As far as possible, the same standards were applied to all of the families and, as a result of the test, 79.4 per cent of the patients were fully justified in their use of the dispensary; 9.1 per cent were doubtful; 8.8 per cent were justified in applying for the services of specialists, as they had no means of obtaining them otherwise; and 12 cases in all, or a little over 2 per cent of the total number, were found to be taking undue advantage of the dispensary. Of those 12 patients, 4 were Negroes, 5 Hebrews, and 3 native born. Of the 50 patients classified in the doubtful group, 16 were native born, 3 Italians, 14 Hebrews, 5 Irish, 2 Slavs, 3 Germans, 3 Negroes and 4 miscellaneous (Table V).

These findings concerning dispensary abuse correspond in a large degree to the results of similar studies made at various times in this and other cities.

In a careful investigation made in 1915 among one thousand patients of the Presbyterian Hospital of Philadelphia, it was found "that in twenty cases out of the one thousand it was felt that the acceptance of the free care offered by the hospital amounted to abuse. In fifteen other cases the absence of definite information or the presence of suspicious circumstances left the question open to doubt. Thus in only thirty-five cases of the thousand, or 3.5 per cent, was 'abuse' judged to be present or probable."[1] In the judgment of the investigators the Philadelphia study demonstrated "with striking force how utterly impossible it would be for the vast majority of those patronizing the dispensary to pay for the kind of treatment and facilities it affords."

Confirmed by Other Studies

In a study of dispensaries conducted by the Illinois State Health Insurance Commission it was found that 4.5 per cent of the patients were recipients of medical charity which their economic status did not justify. In this connection the report states that "it is well to bear in mind that the type of medical service needed is important in determining whether or not a patient is worthy of dispensary treatment. One may be well able to pay a general practitioner for treatment of a minor ailment or one of short duration, but unable to pay for a specialist's services, if needed, or for treatment continuing through a long period."[2]

In 1912 a committee of the Medical Society of the

1. Jobes, R., and Hostetter, F.: A Social Survey of Dispensary Patients in Philadelphia, Mod. Hosp., November, 1915, p. 321.

County of New York made a study of one thousand cases selected from thirteen dispensaries of this city and found that 90 per cent of the patients seemed to be worthy of free treatment and that approximately 10 per cent seemed able to pay for medical treatment under ordinary circumstances, "but the margin over and above fixed expenditures seems in most cases so slight that in illness demanding continued treatment or the services of a specialist, to pay a physician would mean for them serious deprivation or the incurring of debt from which afterwards it would be difficult to escape. In fact, in almost every one of these cases there seems to be a reasonable doubt as to how the case should be regarded. Many people said they were ready and willing to pay a small fee, but their experience had proved the danger and unwisdom of putting themselves in the hands of a doctor of whose skill they were not sure. Many go to the only place they know where they are reasonably sure of correct diagnosis and scientific treatment." [3]

Studies made in other cities yielded similar results. A financial investigation of the resources of 1,881 families in the Boston Dispensary,[4] covering a period of several years, showed that "not over 2 per cent of the applicants at this institution could have paid for the medical care they needed at private rates." Dr. B. S. Veeder, after a study of the patients at the Washington University Dispensary at St. Louis, came to the same conclusion. He believes that in view of the relatively small amount of imposition by the patients, which is less than the average percentage of bad debts incurred in private practice, it would be uneconomical on the part of the institutions to make financial investigations of patients as a routine procedure. This is also the view of most of the dispensary administrators with whom the subject was discussed while the present study has been in preparation.

Reasons for Applying to Dispensary

A great variety of reasons for applying to the dispensary was given by the patients, the causes varying with the type of institutions at which inquiries were made and with several racial groups constituting the dispensary clientèle. It is difficult to classify the reasons into clear cut categories, as they frequently overlap and more than one reason is given in certain instances. A few, however, can be carefully defined: such are, for instance, poverty, ignorance as to where to obtain reliable private medical advice, the reputation of the dispensary, or former satisfactory experience. In Table VI the various reasons have been classified and are given by the institutions at which the patients were interviewed. Of the patients interviewed, 15.1 per cent stated that they had no money for private physicians or were unable to continue the services of a private physician. At Cornell, 59.2 per cent of the patients claimed poverty as the reason for coming to the dispensary.

At Lenox Hill as high as 67.8 per cent gave this reason, and at the Presbyterian 60.5 per cent. The lowest proportions of claims of poverty as a cause of recourse to the dispensary were found at all the special hospitals and at the Lincoln Hospital Dispensary in the Bronx, the New York Hospital Dispensary, St. Luke's Hospital Dispensary, the University and Bellevue Clinic, the Vanderbilt Clinic, and the West Side Dispensary on Forty-second Street. It was to be expected that the special hospitals would show a smaller percentage of those claiming poverty than would the general clinics, because of the higher cost of obtaining services of specialists and the difficulty of meeting this problem even among the middle class. The small percentage of poverty claimed at St. Luke's was probably due to the fact that it is situated in the section of the city where there is on an average a less amount of poverty than in the sections east of Third Avenue, whence the majority of the Presbyterian and Lenox Hill Dispensary patients come.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

AUTOEROTIC PHENOMENA IN ADOLESCENCE. An Analytical Study of the Psychology and Psychopathology of Onanism. By K. Menzies, with a foreword by Dr. Ernest Jones.[1]

The author presents the various views held by authorities regarding the psychology and pathology of masturbation. The author himself is of the opinion that autoerotismi is a rather normal phenomenon during adolescence and is not harmful unless carried to excess. The author advises psychoanalysis in the treatment of excessive autoerotism. In fact, all through the book the author refers constantly to psychoanalysis as the great advance in medicine during the last few years.

One may differ from some of the author's views; it must be admitted, however, that the booklet serves a purpose, namely the review of authoritative literature on an important and much disputed subject.

BRIGHTNESS AND DULLNESS IN CHILDREN. By Herbert Woodrow, Ph. D., associate professor of psychology in the University of Minnesota.[2]

The author considers brightness and dullness in children as due to inborn traits, although he recognizes the influence of social status on the mind.

The author speaks very highly of the Binet Simon test, and tries hard to smooth out all difficulties encountered in the attempt to make it a universal test. All through the book one notices the influence of Binet Simon's work and the influence of Galton's work on the author.

Of great interest is the practical application he gives to the newer knowledge of the psychology of children.

THE FUNDAMENTALS OF HUMAN ANATOMY, Including Its Borderland Districts. From the Viewpoint of a Practitioner. By Marsh Pitzman, A. B., M. D., professor of anatomy in the dental department of Washington University, St. Louis.[3]

The author of this book has attempted to make anatomy easier for the medical and dental student, and has succeeded in no small degree. He explains the meaning of the Latin and Greek terms, gives short and clean cut descriptions of the body structures, and shows the application of many anatomic facts to the practice of medicine.

ÉTUDE CRITIQUE DE L'ÉTIOLOGIE DES BRONCHITES CHRONIQUES AVEC SCLEROSE PULMONAIRE. Par le Dr. Jacques Dalsace.[4]

This study, based on eighteen cases and a review of the literature, is an attempt to explain some instances of chronic bronchitis on a syphilitic basis. The author has evidently made a conscientious effort to prove the tuberculous nature of the lesions, but in the absence of acid fast organisms in the sputum, or in inoculated guinea pigs, has concluded that, inasmuch as a majority of the patients had positive Wassermann reactions—degree or antigen not mentioned—there was presumptive evidence of a pulmonary infection of luetic origin. On several patients with negative Wassermann reactions, syphilis was surmised following several miscarriages.

The author concludes that a diagnosis of syphilis of the lung must be made chiefly on negative evidence of other pulmonary infections, together with an apical sclerosis, large hilus shadows, sputum not containing tubercle bacilli or many organisms of other types, a negative result from guinea pig inoculations, and, preferably, a positive Wassermann. His several autopsies have been undeciding factors, due, he claims, to the difficulty of demonstrating the Treponema pallida in histologic lung sections.

Although some of the patients entered the hospital for relief from dyspnea of an asthmatic type, no mention is made of efforts to ascertain the possible anaphylactic nature of the trouble.

A DICTIONARY OF TREATMENT, Including Medical and Surgical Therapeutics. By Sir William Whitla, M. A., M. D., LL. D., M. P., late professor of materia medica and therapeutics in Queen's University, Belfast, etc.[5]

This handy volume is of proper size to be kept on the physician's desk for handy reference. Its popularity is attested by the fact that thirty-two thousand copies have been printed. While brief and to the point, it is remarkable how many items are included and practically all forms of approved treatment are at least mentioned. It is quite up to date. While not exhaustive enough to serve as a textbook, it is admirably adapted to refresh one's memory.

CARE AND FEEDING OF INFANTS AND CHILDREN. A Textbook for Trained Nurses. By Walter Reeve Ramsey, M. D., associate professor of diseases of children, University of Minnesota; Including Suggestions on Nursing by Margaret B. Lettice, supervising nurse of the Baby Welfare Association, St. Paul, Minn. Second edition.[6]

While primarily a textbook for nurses, this is the type of book which should be in the hands of every mother and expectant mother. It is well written and the numerous illustrations are very helpful. Considerable attention is devoted to public health nursing, both prenatal and postnatal in a special chapter on "Child Welfare." The anatomy and physiology of the infant are treated briefly. The general care, hygiene, and feeding of infants are thoroughly covered. In addition, there are chapters on the abnormalities and diseases of infancy and early childhood.

PUBLIC HEALTH and HYGIENE

By Eminent Authorities

Edited by WILLIAM HALLOCK PARK, M.D.

PROFESSOR OF BACTERIOLOGY AND HYGIENE, UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; DIRECTOR OF THE BUREAU OF LABORATORIES, DEPARTMENT OF HEALTH, NEW YORK CITY

Octavo, 884 pages with 123 illustrations. Cloth $10.00 net

A remarkable advance has taken place, in the past few years, in the appreciation of the people and of their officials in regard to the value of public health. This growing opinion that public health is to a large extent purchasable by effort and money, has stimulated health authorities to develop their opportunities and to assume greater responsibilities. The best medical colleges no longer confine their teaching almost wholly to subjects dealing with the diagnosis and treatment of disease, but give thorough courses in hygiene, and its practical application in preventive medicine. The technological schools are providing similar courses to students thinking of entering the field of public health work.

The great advances in our knowledge concerning hygiene and the increasing scope of public health work have led to the creation of many subdivisions and the problems and practices connected with these have become so highly technical as to require public health workers to restrict their activities to special lines. The medical officer for some time has appreciated this. Wherever the community is large enough to afford it, he has obtained the service of specialists to administer and develop the different departments. The department of health of any progressive State or large city has under the administrative head a number of bureaus, each of these under some specialist who has demonstrated his fitness.

The time has passed when any one person can possess the technical knowledge and personal experience required properly to direct and develop all or even several of these different branches of public health work. It is also true that few if any persons can discuss authoritatively more than one or two of these subjects. The report of the American Public Health Association on the control of communicable diseases was consulted in writing the chapter on that subject.

The writers of this book, holding the above opinions, believed that there was need of a volume in which the most important phases of hygiene in relation to public health would be presented in a practical way by specialists actually devoting themselves to the subjects treated by them. The writers have kept in mind that the book is intended for public health officials, physicians and medical students, and each has therefore tried to make his section as practical as possible and to utilize to the full his own personal experience.

CONTENTS

Relation of Microorganisms to Disease
WILLIAM H. PARK, M.D.

Antimicrobal or Antiprotein Substances Individually Considered
WILLIAM H. PARK, M.D., AND CHARLES KRUMWIEDE, M.D. Assistant Director of the Bureau of Laboratories; Associate Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, New York City.

Prevention of Individual Infectious Diseases

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from Page 774)

MILITARY OPHTHALMIC SURGERY. By Allen Greenwood, M. D., Lieut.-Colonel, Medical Corps, U. S. A.; Including Chapters on Trachoma, Other Contagious Conjunctival Diseases, and Gas Conjunctivitis, by G. E. DeSchweinitz, M. D.; and a Chapter on Ocular Malingering, by Walter R. Parker, M. D.[7]

This handbook was compiled with the idea of presenting in condensed form suggestions helpful to medical officers who had to deal with the special ophthalmic problems which arose in the daily routine of active army medical work. Colonel Greenwood, than whom, by reason of his long service in the British and American military ophthalmic service, no one is better qualified, discusses clearly and succinctly the principle features of military ophthalmic surgery. Colonel DeSchweinitz contributes a splendidly written chapter on "Trachoma and Common Forms of Conjunctivitis." Colonel Parker gives concise directions for the examination and detection of malingerers.

The book served a most useful purpose during the war, and even today is well worthy of perusal.

OXFORD MEDICINE, Volume I. The Fundamental Sciences and General Topics. By Various Authors. Edited by Henry A. Christian, A. M., M. D., hersey professor of the theory and practice of physics, Harvard University, physician-in-chief to the Peter Bent Brigham Hospital, Boston, Mass., and Sir James Mackenzie, M. D., F. R. C. P., LL. D., F. R. S., consulting physician to the London Hospital and director of the Clinical Institute, St. Andrews, Scotland. In five volumes.[8]

When the original announcements were made by the Oxford Press concerning the publication of the Oxford Medicine, they made one's intellectual mouth water in the expectation of the good news to come. Now that the first volume is before us it is fair to ask the question whether the actual response is equal to the anticipated one. This volume on general medicine and the fundamental sciences contains articles, amongst which are Christian, Mackenzie, Hewlett, Billings, Slike, McCollum, Osler, Davenport, Cabot, and Rowntree. This array of names in itself speaks for the type of material presented.

It is, of course, impossible to review in detail such a volume and it would cause invidious comparisons to pick on any single contribution. However, the philosophical discussions of Christian and Mackenzie offer much food for thought.

One wonders whether it is a fair criticism to make, but some of the articles seem too monographic in type. Perhaps interest would be better held if a little more condensation were possible, althongh how to accomplish this it is difficult to see.

Speaking generally, it is safe to say that if the rest of the volumes live up to the standard of the first the Oxford Medicine will become a classical system.

CUNNINGHAM'S MANUAL OF PRACTICAL ANATOMY. Revised and edited by Arthur Robinson, professor of anatomy in the University of Edinburgh.[9]

Ever since we used the first edition of Cunningham at medical school, it has remained the standard dissecting manual. It is as staple as Webster's Dictionary. The make-up has been improved in this edition. Numerous new cuts and skiagrams have been added and the text revised. It now appears in three volumes. The international (B. N. A.) terminology is used.

9. William Wood & Co., New York, 1920.

A Big Story In a Small Nutshell

THE beginning point of many under-oxydation disorders lies in the improper cooking of food, and in the use of lard, animal fats, and ordinary cooking compounds, used in the preparation of food. These fats, because of their low burning point, "decompose" by the action of heat into products other than fatty acids and glycerine.

The acrolein produced by burning is not only intensely irritating to the intestinal mucosa, but also prevents the normal secretion of digestive juices—thereby hampering digestive and metabolic processes, and preventing the proper isomeric transformation of the proteid molecule.

There is one way in which much of this can be prevented. This is by advising your patients to use Mazola in all their cooking and baking. Mazola has a higher burning point than other cooking fats or oils. It can be heated to 650° Fahrenheit, or more, before burning! Whereas, butter, lard, goose grease and cooking compounds burn at much lower temperatures.

Food properly cooked in Mazola is seared over by the heat—not soaked full of indigestible fats. Natural odors and flavors are retained. Food is rendered more digestible. The nutrition of your patient is enhanced.

Mazola is equally valuable as a salad oil, and as an easily assimilated fat—rich in lecithin and in phosphorous compounds—helpful in all wasting diseases, and to assist in conserving the integrity of the protein structure of the body.

Order your patients to use Mazola, Doctor, and note the immediate improvement that follows.

Science Guards Its Purity

In our condenseries we employ every precaution known to science to insure the purity of Carnation Milk.

Due to this fact its quality has always been of the highest standard.

Carnation Milk is pure cows' milk, evaporated and sterilized. Only water is removed in this process.

All the natural food value is retained, nothing is added, not even sugar.

Physicians and nurses can safely administer Carnation Milk to their patients, knowing it to be scientifically pure and wholesome.

A NEW PROBLEM IN EDUCATION

The proper care of the children from two to five whose mothers are forced to leave home to work has been provided in London by volunteer nursing schools in connection with the public elementary schools, thus creating a new problem for educational committees. "The child is not a miniature adult," says the English journal, *Maternity and Child Welfare*. "Food, space, air, freedom to see and hear and touch and handle—these things come first. The nursery school should not be a forcing ground."

THE PUBLIC HEALTH NURSE

The September issue of the *Public Health Nurse* contains a very comprehensive review of the developments of the work of the United States Public Health Service. An interesting account is given of the development of the Bureau of Public Health Nursing in Ohio, by Hulda A. Cron, state supervising nurse, and John A. Smith, M.D., secretary of the New York State Department of Health, Albany, analyzes the several state programs of public health nursing.

AMERICAN JOURNAL OF NURSING

The editorial comment of the October issue of the *American Journal of Nursing* concerns itself chiefly with retrospect, as this issue marks the end of the first twenty years of the journal's existence. The several issues of outstanding importance now before the Society are mentioned and a summary of the entire situation and the measures which the *Journal* has advocated and whose success it has largely brought about are interestingly recounted by Miss Mary M. Riddle, treasurer of the General Board of Directors.

STATE NURSING ACTIVITIES

A summary is made by John A. Smith, M.D., secretary of the State Department of Health, Albany, N. Y., of the various state programs of public health nursing, which appears in the September issue of the *Public Health Nurse*. It is useless, he says, for various state departments to plan programs of public health protection until some means of providing an adequate number of full time health officers and thoroughly trained public health nurses are found. He briefly outlines the essentials of a fairly adequate state program.

New York has made a comprehensive recent study of her problems and has been very progressive in the activities undertaken. Twenty-eight states have adopted a statewide public health nursing program. In nine states the activities of the nursing buerau are combined with those of child hygiene. State supervision of public health nursing is provided in ten states. The county health unit plan of distributing the various states for nursing service has been adopted by fourteen states. In Washington the state law permits county commissioners to employ county tuberculosis visiting nurses and these nurses also do general public health work. Seven states have adopted the plan of distributing the state into health districts for a statewide public health nursing service. One state, Connecticut, has adopted the "town unit plan."

In commenting upon the organization of the work of public health nursing, Doctor Smith regards as essential the adoption of some such plan as that submitted to the National Organization for Public Health Nurses for providing a national public health nurse registry. Through such a registry health authorities would find it possible to secure qualified public health nurses.

The Production of Simmons Beds

begins on the Common sense Principle that a Bed is Made to Sleep in

SOUND, restful, health-building sleep is essential to the harmonious functioning of mind, nerves and muscles.

A bed may be ever so beautiful in design and finish but if it fails to *invite* sleep with its comfort and restfulness, nobody wants to give it "houseroom."

Sound sleep cannot be had in a bed that rattles or squeaks with every turn of its occupant. That is why it is so important to know about and discover faults of this character *before* a new bed is finally purchased.

Simmons Beds are Built for Sleep.

By this, it may be properly emphasized, they are so designed and constructed as to insure the greatest degree of comfort. Each and every part is made to fit snug and tight. The result is that, when the complete assembly of head, foot and siderails is made, there is no sagging or twisting out of alignment. A noiseless, supremely comfortable bed as well as an artistic, harmoniously finished piece of bedroom furniture is what buyers of Simmons Beds get.

Any Simmons Bed you select can be depended upon for strength, comfort and service. The designs vary; there is an almost unlimited array of styles, colors and finishes to choose from—but the basic construction is always the same, always sanitary, correctly proportioned and luxuriously comfortable.

Physicians, Public Health Officials, Nurses and Welfare Workers everywhere, men and women who know and appreciate the importance of sound, restful sleep, are enthusiastic about the superior sleep qualities of Simmons Beds; and there is a design and finish to harmonize with the furnishings of any home.

The Booklet "Yours for a Perfect Night's Rest," illustrating and describing Simmons Beds for modern homes, will be mailed upon request.

The Right Flavor

It is the flavor that makes nourishing foods and drinks palatable. And it is important that they be palatable in order to promote digestion and assimilation.

Physicians and dietitians who recognize this fact insist on the use of only the best flavors. Many of them recommend

SAUER'S
THE NATIONAL EXTRACT
VANILLA AND 32 OTHER FLAVORS

They are made from the choicest materials obtainable in a modern and sanitary plant where every care is taken in their manufacture.

Sauer's Extracts have won seventeen highest awards and medals at American and European Expositions for purity, strength and fine flavor.

The C. F. Sauer Company

Richmond, Virginia

RED CROSS TOUR OF INSPECTION

Miss Clara D. Noyes, director of the American Red Cross, recently sailed for Europe to undertake an extended tour of inspection of the Red Cross activities in Europe.

HELPS DETROIT CRIPPLED CHILDREN

A million dollars to finance a free hospital for crippled children was set aside in the will of the late George H. Cummings, former president of the Detroit Rack Company, executors of the estate recently announced. Mr. Cummings was once a country school teacher.

FINDS HOME FOR SICK NURSES

Nurses who are ill as a result of their service in the war have been provided at The Evergreens, a beautiful twelve acre country estate overlooking Great Shore Bay along the shore of Long Island, N. Y., a place where army, navy, and Red Cross nurses may be cared for during convalescence after illness incurred during the war.

CARE OF THE GROWING CHILD

Supplementing the recent propaganda on the care of the baby, the United States Public Health Service has inaugurated a campaign of education for the promotion of child health. A large number of special articles have been prepared and distributed to more than one hundred newspapers for publication in serial form. This series will appear under the title of "The Growing Child" and deals with a wide variety of subjects pertaining to the health of the child.

WOMEN AND GIRLS FIRST

Red Cross instruction in Home Hygiene and Care of the Sick, which was given to 92,000 women and girls during the last fiscal year, will not for the present be stimulated to include boys and men.

Many requests for the establishment of classes have come from brothers, fathers, and husbands, to whom the influenza epidemic brought vital realization of their inability to care for stricken members of their families. Owing to the lack of qualified nurse instructors, Red Cross National Headquarters has reached the decision that the expansion of this course to include this group would not for the present be advisable. Exceptions to this rule are being made, however, in the case of missionaries, who have found the knowledge of household hygiene and elementary nursing procedure of inestimable value in their work.

PUBLIC HEALTH NURSING IN ITALY

The three courses in public health nursing established by the American Red Cross Tuberculosis Association in Italy are meeting with marked success, according to the *American Journal of Nursing*. The first course was in Rome. A new course is being opened this month in Milan, and the ten months course offered in Genoa closed in October. The graduates from all three courses are in such demand that there are constantly more positions than candidates.

Some Italian students will be brought to America within the next year to see how our public health nursing is done. The scholarships permitting them to do this have been secured through Dr. William Charles White of Pittsburgh, the director of the American Red Cross Tuberculosis Commission in Italy.

Foods entirely free from Starch and Sugar can easily be made from Listers Prepared-Casein Diabetic Flour
We do not furnish the cooked foods

DIABETIC BREAD Cookies Muffins Pastry

warranted palatable non-carbohydrate foods are easily made in any home from

LISTERS PREPARED-CASEIN DIABETIC FLOUR

Absolutely Starchless

YOUR diabetic patient can enjoy a much more varied, satisfying and healthful menu by the introduction of the many delicious, strictly non-carbohydrate foods that can be made from Listers Diabetic flour.

NOT A GLUTEN FLOUR

—but a blend of special caseins, made by our own exclusive process. Absolutely starch-free, sugar-free and purin-free. Easily digested—about 95% is assimilated and 90% goes into energy.

SELF-RISING. Packed in small, carefully weighed boxes—each containing the correct protein-content, per day, for the average patient—and accompanied by carefully tested recipes for making the various foods.

Listers Flour, being non-carbohydrate, is a valuable aid in rendering the patient sugar-free; and also—afterward—in determining the specific tolerance of the patient.

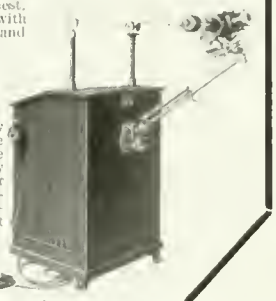
L-F Coolidge X-Ray Units

Model 530, $960

Expressly adapted to needs of the oral surgeon, who requires films or plates of the frontal and maxillary sinuses as well as intra-oral films, or for installations where both dental and routine medical work is to be done. Fully counterbalanced tube holder. Capable of doing all radiographic work, including chest, stomach and intestinal tract. Equipped with magnetically operated exposure switch and combination cone

30 M. A., Variable Gap, 3 to 5"



Model 310, $650

10 M. A., 3" Gap

Expressly adapted to strictly dental radiography, having the advantages of the right angle Coolidge Tube. Especially easy and rapid adjustments for intra-oral work; fully counterbalanced tube holder, the complete equipment very compact and easily moved about. Can be operated either with patient in dental chair or separate chair

Operates off ordinary light wiring

Both outfits are equipped with the L-F automatic switch, which makes possible the accurate timing of all exposures, insuring uniformity of results.

Rochester, N. Y.

MICHIGAN TRAVELING HEALTH LABORATORY

The Department of Public Health of Muskegon, Mich., recently made a survey of health conditions of Muskegon County resorts, using in the work a truck containing a fully equipped laboratory. Special attention was paid to water and sewage disposal. Impurity of water supply was found at numerous resorts.

FLORIDA EXTENDS HEALTH PROGRAM

Under a new campaign recently inaugurated by the Florida State Board of Health, the health work will be carried directly into the homes of the citizens with particular emphasis in the remote rural districts. Field directors will work simultaneously in several adjoining counties directed by an experienced director of rural sanitation, and a campaign to correct any defects discovered after careful survey will follow.

CALIFORNIA HAS MOTOR CLINIC

The California Tuberculosis Association announces that the Traveling Motor Clinic promised the people of the state will become a reality the first of September. When finished it will be the most complete clinic in the United States. It will have hot and cold running water, two dressing rooms, scales, examination room, moving picture machine, electric stove for winter and fan for summer. It will be used for educational purposes as well as for a clinic.

DENTISTS REPORT VENEREAL DISEASE

In the campaign instituted in the Fall of 1919 among the forty thousand licensed and registered dentists of the United States, a circular letter addressed to each specifically requested the report of all venereal disease observed by them and the reference of such cases to a clinic or a reputable physician for treatment. With the close of the fiscal year (1920) 15,252 dentists of the forty thousand circularized had pledged themselves to report all cases of venereal disease in accordance with the laws and regulations of their states.

MARINE HOSPITAL OPENED

The Marine Hospital, starting with 130 beds, has recently been opened in Chicago and will act as a general clearing house for soldiers and sailors residing in the states of Illinois, Wisconsin, and Michigan who are suffering from nervous and mental diseases. The hospital will be in charge of L. M. Wilbur, M.D., surgeon of the Public Health Service, who has had a distinguished record, particularly in New York, where he served in both private and state hospitals and in the well known New York Neurological Institute.

THE CONTROL OF SMALLPOX

For many years smallpox has been regarded by the people of the United States as a disease that had lost its old time terror, but in 1919 more than two thousand cases were reported in California, and the disease was also found to be prevalent in some of the southern states. In the Province of Ontario, where there has been persistent opposition to vaccination, there was a severe outbreak of smallpox early this year. Here is a condition which may well be viewed with especial concern as a situation calling for activity in promoting sentiment in favor of the passage of law where needed to secure general vaccination, and to support the health authorities in their efforts to see that existing laws are properly enforced.

The Efficiency of Our Employees

Is Reflected in

The Efficiency of Our Product

Scientific apparatus represents more than a combination of material and labor. The interested, efficient, and intelligent cooperation of the workers is needed to produce efficient apparatus.

We have secured such cooperation.

We pay a bonus on production—we penalize defective workmanship.

The man who will not earn a bonus is not wanted. Every employee is an efficiency engineer.

With such support from our organization, the production of QUALITY apparatus is a natural sequence.

Let us tell you about the QUALITY in

Breakfast

One Cent per Dish

Quaker Oats costs one cent per dish. Two eggs cost 8 cents—one chop costs 12 cents.

Quaker Oats yields 1810 calories of nutriment per pound. Round steak yields 890.

Quaker Oats costs 6½ cents per 1,000 calories. Average meats cost 45c, fish 50c, eggs 60c.

Quaker Oats forms almost the ideal food in balance and completeness.

From 9 to 10 people can be fed on oats for the cost of feeding one on meat foods.

To make Quaker Oats the basic breakfast means better feeding and a great economy.

Quaker Oats

The leading brand the world over because of its flavor. Flaked from queen grains only—just the rich, plump, flavory oats. We get but ten pounds from a bushel.

The Quaker Oats Company

Chicago

SCIENCE IN INDUSTRY

The United States is no longer dependent on other nations for essential chemicals, owing chiefly to the quickening of American invention by means of the application of ingenuity in both pure scientific research and its application to industrial processes. The maintenance of highly equipped laboratories is not confined to the Government but has become customary with leading corporations. Among the achievements during the past year may be mentioned dyes, potash, medicine, and other chemicals and fertilizers; also lenses and many kinds of machinery. In radio and other electric lines there has also been notable progress.

CANCER IN SWITZERLAND

The *Deutsche medizinische Woehenschrift* is reported as commenting on a recent compilation of cases of mammary cancer in Switzerland, stating that cancer is so prevalent in Switzerland that every twelfth person more than thirty-five years old faces the prospect of dying of cancer. In a recent five year period, gastric cancer formed 37.9 per cent of the cases; cancer of the female genitals, 16.1 per cent; and mammary cancer, 10.6 per cent. The average survival of the operative mammary cancer cases was a little less than five months.

THE MARION NATIONAL SANATORIUM

A unique medical enterprise has been carried out in the accommodations provided by the new mental hospital which was opened at Marion, Ind., early in November. All types of mental diseases will be treated there, from the mildest to the most serious and chronic conditions. The sanatorium will not be a military institution, although its officers have been chosen almost entirely from those who served in neuropsychiatric work during the war.

Plans for the care of the patients include diversions, occupational therapy, and the systematic cultivation of athletics and physical training. Every possible occupation which can be used to arouse the interest and promote the recovery of the patients will be employed and, as soon as complete or partial restoration seems to be in sight, a strongly vocational training will be given to all of the previous activities previously carried on as therapeutic measures.

IMPROVE DIAGNOSTIC METHODS

The United States Public Health Service, which for some time has been making special efforts to facilitate the diagnosis of tuberculosis and especially to bring about its recognition in its very earliest stages, has recently opened mobile training courses for the purpose in Illinois, Wisconsin, Michigan, and Washington. Similar courses have already been given in Texas, Louisiana, Missouri, Virginia, West Virginia, Maryland, and Pennsylvania. These courses, which last seven days and are very intensive, are at present open only to physicians attached to the Public Health Service; but after all of these in the various states have completed the course it is hoped that it may be possible to hold similar courses for the benefit of other physicians who may desire to attend.

The instruction is given by recognized experts in the diagnosis of pulmonary tuberculosis, and is supplemented by the showing of a remarkable motion picture, in six reels, which minutely illustrates every phase of the disease. By such means it is hoped that disease detection will keep pace with municipal facilities for the care of tuberculosis.

SCIENTISTS HUNT NEW DRUGS

According to an announcement recently made by Henry H. Rusby, M.D., dean of the Columbia School of Pharmacy, beginning in January, a party of American scientists will explore about one thousand miles of the Amazon basin in search of new drugs and narcotics, the expedition to be called the Mulford Biological Exploration of the Amazon.

The investigations of the party will be on a purely scientific basis and the general aim will be to make discoveries of an economic value. Insects and animals are to be studied as well as medicinal plants, and photographers will make educational motion pictures.

Doctor Rusby has already made four trips to South America. Before the war he went into southern Colombia to study quinin sources. In 1885 he started a two year expedition to the Amazon in search of medicinal plants. He explored the Orinoco delta for a colonization company in 1893, and on another expedition he sought new sources of rubber supplies. "There remains this one thousand mile tract along eastern Ecuador and Peru from which no specimens of any kind have ever been produced," said Doctor Rusby.

CLINICAL CONGRESS MEETS

The Clinical Congress of the American College of Surgeons had a very felicitous opening in the occasion of the presentation to the College of a mace, symbolic of the best traditions of both Britain and America, and embodying best objectives of the medical profession, which was offered by the Consulting Surgeons of Great Britain as a mark of appreciation of the service of American surgeons during the great war and as an earnest of the continuance of cooperative work between Britain and the United States for the advancement of science.

Dr. William J. Mayo, as retiring president, gave the assembly an analysis of statistics regarding mortality rates after operations for cancer. Allowing for percentages of error, and for variations of records, his deductions pointed out the lines for future progress in lessening mortality after operations. He considered that with such advances as the use of radium, and catgut instead of silk for sutures, operability has increased. While mortality rates may have seemed to grow, the average resultant longevity of the patients has increased, and that the broad result has been beneficial. Dr. Mayo advised the extension of the group medical system to include both medical and surgical work, which would have the advantage of bringing the patient earlier to the service where he would receive the most benefit, and would overcome many of the evils of competitive medicine.

The presidential address of Dr. George E. Armstrong was a treatise on the changes in cell life, the action of colloids, chemical and physical reactions, working out in scholarly fashion many details of this abstruse question.

The John B. Murphy oration was given by Sir Berkeley Moynihan. Beginning with a eulogy of Dr. Murphy and his work as revolutionary in certain important fields of surgery, Sir Berkeley proceeded to an historical sketch of surgery, emphasizing certain notable discoveries from time to time. He showed each successive achievement as growing out of the work of the past. New discoveries are rarely the work of one man, but are worked out in groups. Lister he characterized as the greatest man in the world of medical science, inasmuch as he had by his discoveries transferred surgery from the "pathology of the dead" to the pathology of the living.

The nutrient value of VIROL illustrated in a number of cases, particulars of which have been supplied by medical men.

After being fed on VIROL regularly for five months he is a fine, strong, healthy boy. The Doctor says:—"I have pleasure in confirming the statement of the wonderful improvement made by this child after feeding on VIROL. I feared his case was hopeless."

Maurice Pickering was suffering from blood poisoning. His lungs were also affected. He wasted worse than he appears in above photograph.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

Viral is a valuable food for invalids and children. It is a preparation composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble Phosphates.

In glass jars:
50c, $1.00 and $2.00

CONCENTRATED FOOD—A well-known medical man writes as follows: "I have never prescribed a better tissue builder than VIROL and I have been in active general practice for over forty years."

The fat in VIROL is so minutely divided that it is more readily absorbed than milk.

UNIQUE GRADUATE MEDICAL SCHOOL

Two hundred of Philadelphia's medical men and surgeons, many of them eminent, are about to share their professional secrets with their less successful brothers through the medium of the graduate school of medicine at the University of Pennsylvania. There is no other school in the United States where so many eminent men take part in routine class room and clinical programs for teaching purposes. Virtually all of Philadelphia's hospitals will be used as clinical laboratories in addition to the clinics and laboratories of the University of Pennsylvania. Research will be nourished, but the major effort will be made to spread the influence of the best present knowledge and skill in the curing of human ills. A limited number of research scholarships are offered in bacteriology, immunology, chemotherapy, pathology, and biochemistry. The holders of these will give their entire time to original work which will be selected and approved by the dean, the vice-dean for medical sciences, and the director of the particular laboratory.

PROTECT THE ILLEGITIMATE CHILD

Action taken by the National Conference of Commissioners on Uniform State Laws at the annual meeting of that organization in St. Louis on August 19 promises that a uniform act will be drawn for the protection of children of illegitimate birth. The principles that should underlie legislation relating to children of illegitimate birth have been worked out under the auspices of the Children's Bureau and the Inter-City Conference on Illegitimacy. Social workers, judges, lawyers, and others have valued, concrete suggestions on the subject and general agreements have been reached regarding the best methods of dealing with the fundamental problems involved.

The *Survey* for September 15, 1920, summarizes the results of the several conferences on this subject. The drafting by the Conference of a standard law or laws covering the basic principles that should be incorporated in the laws of the various states will be of great value to all of the states in framing legislation.

CANCER IN DYE WORKERS

There are circumstances which point very directly to a mechanical cause for some tumors. In the extension of the dye industry in America we are confronted with the possibility that hitherto uncommon forms of cancer will appear and many of these may be attributed to chemical stimulation. Dye workers cancers, says the *Journal of Laboratory and Clinical Medicine*, are interesting because of the fact that they are apparently of pure chemical origin and because they are of very long incubation, appearing to be due, in the case of bladder tumors, to the long continued action of a dilute material excreted by way of the urinary tract, which affects only the mucous membrane of the urinary bladder. This irritating substance, or the ones from which it originates, may be taken into the body through the skin, the respiratory tract, and gastrointestinal tract, and is generally supposed to be anilin or fenzidin. Nassauer believes anilin to be the specific agency and holds that workmen should not be exposed for more than three months. He also believes that by enforcement of proper rules of sanitation, including personal cleanliness, most of the danger can be avoided. In a factory which Nassauer has studied, in which many cases formerly occurred, no case has appeared in a period of fourteen years since the inauguration of strict hygienic requirements.

Sixty Years of Faithful Service to the Medical Profession

From the inception of our business we have ever sought the friendship and confidence of physicians, and whatever results we may have obtained, we do not hesitate to attribute largely to the splendid co-operation that has been given us by the medical profession.

Therefore, in calling attention to this—our Sixtieth Anniversary—we wish to thank our many medical friends not only for their unfailing interest and good will, but also to assure them that, as in the past, we shall continue to regard their confidence as "our greatest asset."

FRENCH PHYSICIANS INFLUENCE LEGISLATURE

The medical members of the French parliament hold regular meetings and have recently been able to influence legislation on public sanatoriums. The points on which they especially insisted were that the board of nine members which examines and classifies candidates for posts as sanatorium physicians should include a representative of the medical school of the region, and a representative of the national medical association and of the national *Union des syndicats médicaux*. Also, that a representative of the medical faculty form one of the superior board of five members. The supervision of the public sanatoriums is not to be left to public health officers, but to form part of the duties of the professor of hygiene in the nearest medical school. The medical parliamentary group was also successful in its plea to have the salaries of sanatorium physicians 9,000 and 14,000 francs to start with.

AN AUTO VICTIM EVERY HALF HOUR

Public opinion must be thoroughly aroused through systematic and persistent safety education, declared C. M. Talbert recently before the Congress of the American Electric Railways Association. Ninety per cent of all accidents may be said to occur in public highways, and automobile fatalities have grown from nine per million population, to 110 for each million inhabitants in 1920, or in the United States, one death every thirty-one minutes of the sixteen commonly allotted waking hours.

The total of vehicular accidents increased from 245 per million in 1906 to 253.3 in 1919, while all other forms of accidents decreased 18 per cent. Mr. Talbert advocated as a remedy a direct appeal to "public psychology" and declared that the most fruitful ground for ultimate results is in public and parochial schools.

INTERNATIONAL LABOR PUBLICATION

Albert Thomas, director of the International Labor Office, League of Nations, has sent an official note to members of the Governing Body, Governments, and organizations of workers and employers throughout the world, stating that in accordance with the program of the Director submitted to the Governing Body, the Office has undertaken two series of publications—a monthly scientific review and a daily publication.

The monthly *Review* will be modeled after the official publications of various departments of labor and official statistical bureaus and will be devoted to studies of questions concerning industry and labor, presenting them from the international aspect.

The daily publication will be a bulletin of information concerning the progress of the work of the Office and will contain (1) a daily review of the press, (2) a weekly bulletin of general information, and (3) studies and documents, periodically. In order to classify these studies, they will be divided into twelve series, as follows: (a) social life; (b) economic life; (c) progress of labor; (d) conditions of labor; (e) social insurance, including war victims; (f) industrial hygiene; (g) living conditions; (h) cooperation; (i) protection of women and of the race; (j) education; (k) agriculture; (l) marine.

In addition to the above mentioned publications, the Office will issue from time to time, books on special subjects such as "The Inquiry into Conditions of Employment in Soviet Russia," "The Inquiry into Conditions in Hungary," "The Inquiry on Production," which are now being made, reports of Conferences, etc.

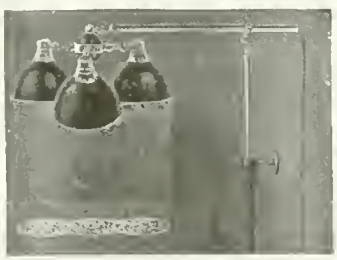
THERMOLITE

A Modern Necessity

The scientifically designed therapeutic lamp is an essential part of today's curative equipment. ThermoLite the lamp that delivers radiant light and heat in PARALLEL RAYS—has proved its merits and won the endorsement of physicians and hospital authorities everywhere.

It relieves pain, reduces inflammation and promotes healing.

The parallel rays of the ThermoLite insure a deepness of penetration which means quick relief. ThermoLite is supplied in two forms—Triplex for hospital, clinic and office use, and Simplex (single lamp, with or without stand) for home use.



Showing **Triplex** adjusted for concentrated application without focusing rays.

Write us for prices and our free book "Photo Therapy."

WORKERS IN SIGHT CONSERVATION

One of the great difficulties in the way of effectual work among those suffering from defective vision has been the shortage of trained workers, a handicap which will be in part overcome by the provision at the Graduate School of Education, Harvard University, in cooperation with the Massachusetts Department of Education, the Perkins Institution for the Blind, and the Adult Blind. The lectures and demonstrations are designed to give in a short period a comprehensive survey of the general field of work with the blind and the semi-sighted. Particulars in regard to the sessions may be learned from Miss Lotta S. Rand, 17 Lawrence Hall, Graduate School of Education, Harvard University, Cambridge, Mass.

COOPERATIVE RURAL HEALTH WORK

A summary is made in *Public Health Reports* under date of October 1, of cooperative rural health projects carried out during the year ended June 30, 1920, in thirty-one counties and eleven states. The fact that the Federal funds contributed to these projects have in all cases been made with odds of about five to one indicates unmistakably that such investments of Federal funds stimulate to a significant degree state, county, and municipal governments to invest in the business of rural health promotion.

The summarized results show unmistakable value to the community of these projects generally, and the total cost of saving the life of an American citizen by such means as estimated at sixty-six dollars seems a reasonably good investment.

SAIL FOR MEDICAL CONGRESS

Among the American physicians who went to Paris to attend the International Congress on the Classification of the Causes of Death were: Haven Emerson, M.D., former health commissioner, representing the Public Health Association; F. J. Monaghan, M.D., assistant health commissioner, and W. H. Guilfoy, M.D., director of the Bureau of Vital Statistics of the Health Department, who represent the city of New York; and Otto Eichel, M.D., of the Bureau of Vital Statistics of the State Department of Health.

The convention meets every ten years for the proper classification of diseases by agreed names, so that each nation can be assured of the causes of death in other nations, and there will be no confusion of names. The Congress has been called by the French government and will last ten days.

ELECTRO-THERAPEUTIC ASSOCIATION

The Thirtieth Annual Meeting of the American Electro-Therapeutic Association was held in Atlantic City, N. J., September 14 to 17, 1920. The breadth and scape of the scientific papers were of the greatest interest, indicating the specific value of electrotherapeutics and its relation to general medicine. Dosage, technic, standardization, and details of apparatus were interspersed with discussions on dietetics on interpretation of radiographs and the rôle of radium in malignancies. "The Relation of Physiotherapy to Industrial Medicine" formed the subject of the thesis of F. G. Granger, M.D., Boston, and its use in the treatment of industrial disability was presented by William D. McFee, M.D. An interesting section dealt with the treatment of exophthalmic goiter, and "Graduated Exercises in Functional Heart Disease" was dicussed by Maj. B. W. Carr, M.C., and "Myocardial Degeneration" by Albert E. Roussel, M.D., Philadelphia.

MEDICINE AND THE LAW

ARE we keeping abreast of the demand in this country in the training of physicians and health workers in the newer phases of medical jurisprudence? In these times the much overworked term "revolution" might be truly applied to the changes which have taken place in the relationship of the physician to the law.

Just to cite the example of the workmen's compensation laws is sufficient to prove the "revolution." Surgeons and neurologists, particularly, have been placed in the new position of refereeing in all kinds of complicated physical and mental cases. Lay boards are passing upon medical questions with or without expert medical counsel and a body of opinion has grown up in commissions and courts which has an important bearing upon the training of physicians. Yet a small degree of attention has been paid by medical schools, periodicals, and books to these new phases of medical and legal aspects.

There is also a rapidly increasing relationship between the administration of justice in courts and the medical profession. The movement extends to all countries where scientific criminology has begun to appear. This advance is admirably summarized in the *Lancet* (London) from the address of Sir Richard Atkin, president of the Medico-Legal Society.

He referred to medical jurisprudence as the large body of medical and surgical knowledge applicable to the elucidation of issues determined in courts of law, and commented on the frequency with which doctors are called upon to give evidence. It was painful, he said, to see a medical man sometimes defeated on his own ground by a member of another profession who happened to have a special and perhaps very recently acquired knowledge of the subject; similarly, it was distressing to see a young man, possibly intrusted with a brief for the first time, incapable of making his point against the defense of an expert medical witness. The tendency now was for medical evidence to become more and more prominent in the trial of certain issues; the effect of physical conditions upon conduct was more emphasized, and motives were expressed in terms of pathology. In criminal law offenses against the person frequently necessitated medical evidence. The judge tended to regard the medical man not as an advocate of either side, but as an officer of justice there to help the court in the elucidation of truth. In the instance of murder, he said, it was only occasionally that doubt arose which could be solved by medical evidence, as only the motive of crime was usually in question; but in almost any murder case the question of insanity might be put to a practitioner by the prisoner's counsel. With regard to charges of wounding, which were very numerous, the proof of intention of causing grievous bodily harm was largely dependent upon medical evidence; in this connection, too, arose the vexed question of the state of mind induced by drunkenness, in which condition a large percentage of these crimes were committed. The most difficult class of cases in which medical men must appear were charges of rape and general sexual offenses. The particular issue of virginity was known to be one of uncertainty, and great injustice might be inflicted either upon the complainant or defendant; the medical witness should go no further than he could with complete satisfaction to himself. It would, he considered, be in the interest of the practitioner for the court to have recourse in these cases to the services of its own surgeon—that there should be one man in the district, recognized as an authority in medical jurisprudence, who could relieve the private practitioner of this difficult task. Another important class of cases is that of abortion, a practice the public danger of which necessitates great care in the reporting of suspected instances. In the case of insanity the medical and legal views might be said to differ; a most important move would be the agreement of the professions as to some formula commending itself to both. The question which divided them —namely, that of criminal responsibility—had perhaps been considered too much in relation to murder alone. Other difficult cases requiring medical evidence were those of divorce, those arising under the Workmen's Compensation Acts, and those relating to all departments of public

health—difficulties involving the skill of the lawyer equally with that of the doctor. In neither profession were sufficient pains taken to develop this relation between them. Sir Richard Atkin concluded with the suggestion that medical jurisprudence might be made a post-graduate subject for medical men.

FEDERAL AID TO THE STATES

AT THE recent convention of American bankers at Washington the idea was strongly advanced that Federal aid should not be granted to the states and local communities for work carried on by them. The idea was evidently inspired by a financial man's fears of public expenditures and did not take account of the century of practical and successful experience in Federal aid legislation through which we have passed.

Federal aid or "grants in aid" as it is sometimes called, is an effective means of stimulating the doing of work locally which the Nation wants to have done. It is a form of partnership into which the nation and the states or local communities enter. The nation—the non-resident partnership—offers funds to the states to do a desired piece of work. The state accepts the funds and the responsibility for doing the work as the Nation desires it done. Here is an effective combination to promote work of mutual advantage. Grants in aid by the states and by national organizations to local communities have everywhere proved a practical success.

In the realm of health work the union of national aid with local effort is especially important. Disease knows no boundaries. A local epidemic may become a national menace. Surgeon General Cumming of the United States Public Health Service has expressed himself vigorously on the national phase of the health problem in commenting upon the proposals by the bankers when he called such a policy "shortsighted." "In health work, especially," said the Surgeon General, "it is extremely important to recognize that the prevalence of communicable diseases in one part of the country is of very direct influence on the people elsewhere. Thus the investigations of the United States Public Health Service have clearly shown that the use of a polluted water supply in some remote rural district has often resulted in extensive outbreaks of typhoid fever in large cities hundreds of miles away; the presence of malaria in certain parts of the South has exacted a heavy economic toll from the country as a whole, for example, by raising the cost of cotton to the consumer; the northern investor has paid dearly for the continued prevalence of hook worm disease in various parts of the country, for where this disease prevails labor efficiency is seriously reduced. When the circumstances are carefully studied it is clear that the control of disease is not merely a local responsibility, but a joint responsibility of Federal, state and local authorities.

"For every dollar of Federal money spent, we have secured five or six dollars worth of effective health work. Under the cost-sharing principles of the existing law the Public Health Service has been able to effect very great sanitary improvements at a very minimum of expense. It is the judgment of all who have studied the results of this cooperative effort that the principle of the Federal aid extension under which this work has been carried on is not only thoroughly sound but has proven of the highest benefit to the country as a whole."

EXTENSION OF MEDICAL SERVICES

THE communication from J. Middleton Martin, B.A., M.D., Medical Officer of Health and School Medical Officer of Gloucester, England, presented on page 808 of this issue of MODERN MEDICINE, gives with interesting detail the initial unit of a complete medical service which formed the basis for the health center scheme as developed for the whole of England. Designed to meet medical needs as indicated by a comprehensive survey, utilizing such agencies as were already available, coordinating these, and providing the machinery for consultative service and future extensions in the way of adequate hospital and laboratory facilities, medical service was rendered immediately much more effectual and a flexibility assured to take care of future developments. The scheme just launched for the establishment of referee consultants will not disturb the primary organizations or interfere with the responsibility of the local practitioner for the welfare of the patient. If practitioners avail themselves of these facilities medical service should be greatly improved, and with the addition of consultant service with adequate hospital accommodation, the service will be considered complete.

The success of such a scheme depends on cooperative effort throughout, but it affords a solution of the difficulties in the way of adequate medical service for outlying districts.

If the hospitals of the country are really to evolve as "centers for the prevention and cure of disease, and for the promotion of medical science and education," it will be accomplished through some such means whereby isolated districts will become an integral part of the general medical service so that the latest and best achievements of research may be available to the whole population. We commend Dr. Martin's article to the careful attention of our readers.

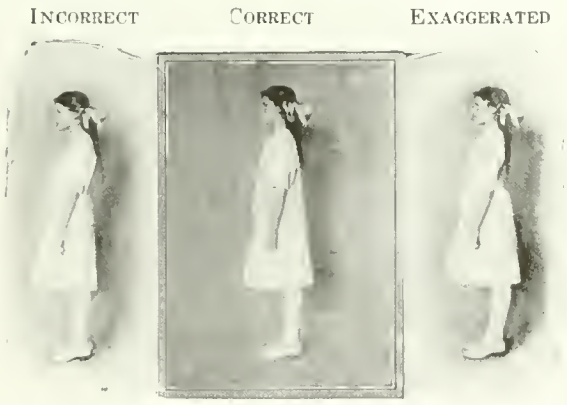
THE AMERICAN POSTURE LEAGUE: ITS HISTORY, WORK AND FUTURE*

By HENRY LING TAYLOR, M.D., New York City

FOR a considerable time thoughtful hygienists, physical trainers, and physicians have attributed much importance to correct carriage of the body as an important factor in maintaining health, comfort, and efficiency.

The body, viewed as a working machine, must have its parts adjusted to each other so that the work in hand may proceed efficiently, and so that its own internal functions shall proceed naturally and without excessive wear and tear or fatigue.

The adjustment of posture and movements to work has been studied with interesting results by Gilbreth and others, but much research is still desirable on the effect of special postures, when long continued, on the internal functions of the body. In general the problems are those of an occupation with too much sitting or standing, insufficient variety of exercise, and too much fatigue, and scientists cannot but approve the efforts of workers and employees to better their conditions. Up to now the main thought has been to increase output, and to scrap worn out machinery, material or human, as considered necessary. It is beginning to be clearly recognized that care of the worker and his tools is equally necessary, and that it pays as a business proposition to eliminate undue fatigue.



All members of the League are furnished copies of boy and girl charts which make a direct and constant appeal for correct habits of posture.

Specifically, in sitting or standing, if the body is habitually bent over, giving a round back, the lungs, heart, and digestive organs are cramped in their action and do not do their work so well. In order that these and other organs may work properly it is necessary, therefore, that the body, at least most of the time, shall be held erect in sitting and standing. It has long been recognized that all slouchiness of posture or morale must be trained out of the recruit in order to make the efficient soldier ready and able instantly to translate the word of command into action.

We are not and we trust never will be a military nation, but we have an army of over twenty million school children under constant training and under governmental orders. How can these children be confined to a seat five or six hours a day without grave bodily harm? Physical training of various sorts has proved helpful, but not a full solution of the difficulty. Games, sports, occupations, recesses, contribute to the well being of children; but posture training must be definite, resulting in habitual postures which shall be free and erect, insuring free play of lungs, heart, and abdominal organs, and elimination of waste. All this increases vigor and efficiency and diminishes fatigue.

This was the general point of view of the educators, hygienists, and physicians who in 1913 associated themselves as the American Posture League to increase interest in the improvement of habitual posture and to set up standards of posture training and to investigate the influences of the immediate personal surroundings such as seating and clothing on posture and to improve these conditions.

The League was incorporated in 1914 under the presidency of Miss Jessie H. Bancroft, director of physical training in the Brooklyn schools. Committees on clothing, shoes, and seating were then appointed. The League was fortunate in including among its officers and members a number of experts who had already made valuable contributions to the subjects given them to investigate, and much time and thought and energy were given to research, especially in the problems of seating, clothing and footwear.

Design Clothes on Anatomic Lines

It was found that many commercial readymade suits for boys were made on round backed models, making it difficult for a straight boy wearing them to stand erect. After conference with an important manufacturer, his coats were re-designed to an erect model, thus favoring correct carriage of the body. Children's waists, maidens' and women's corsets and hose supporters

*The fourth of a series of articles on National Health Organizations prepared for the pages of Modern Medicine.

have been designed in cooperation with a manufacturer, and anatomic models have been constructed which avoid cramping and are supported from the pelvis above the hip bones or from the shoulders near the neck, avoiding any drag on the tip of the shoulder or constriction of the waist.

The technical committee on shoes, after a study of the shoes and lasts on the market, concluded that a study and, if possible, a classification of the forms of feet was necessary. Through the cooperation of teachers, clinics and the Young Men's Christian Association, tracings of several thousand average feet were secured and classified. These tracings included many feet from India and China that had never worn shoes. If these tracings were bisected at the heel, and this axis prolonged forward to the front of the foot, it was found that some feet flared outward from this axis at the ball, some inward, and in some this axis divided the forefoot into equal parts. As the unshod feet fell into these categories as well as the shoe-wearing feet, and the characteristic was showed by both men and women, it was concluded that feet could be divided into the inflare, straight, and outflare types; and lasts embodying this principle, eliminating the pointed toe and high heel and embodying other anatomical features, have been designed in cooperation with shoe manufacturers. These shoes for both men and women are now on the market and are giving great satisfaction.

STANDING POSTURES
INCORRECT POSTURE
The neck and trunk form a zig zag line
CORRECT POSTURE
The neck and trunk form a straight, vertical line
EXAGGERATED POSTURE
This posture can be held only for a short time and with great effort
POSTURE
No. II

It is emphasized that good posture is expressive of courage, endurance, alertness, hope, joy, and the higher emotions.

The technical committee on seating has given much attention to the anatomy of seating and in cooperation with furniture architects has embodied the necessary anatomical features in the Brooklyn Rapid Transit Subway seats, school seats for the various classes and ages, industrial furniture, and office furniture. Owing to war conditions and other causes, the furniture manufacturers have been slow to cooperate, but it is possible to secure various lines of this furniture on special orders.

The League wishes to express its indebtedness to many manufacturers who have freely given of their experience and facilities. In several instances, these manufacturers have made a considerable investment of capital in this untried field which seemed to them, as it has to us, to offer great possibilities, not only of public benefit, but of a substantial return. We are also deeply indebted to the experts who so freely gave of their time and technical knowledge without reward other than the consciousness of having added to the sum of human betterment.

INCORRECT CORRECT EXAGGERATED

Relaxed and poor posture suggests physical or mental weakness, dejection, cowardice, fear, and deceitfulness. Figures in good posture need not be in static military attitude, but may be active or passive.

Work Is Educational

The educational work of the League comprises the publication of a series of posture wall charts, the collection of posture photographs, including school and industrial pictures, lantern slides for lectures on posture, and other illustrative material. Much of this has been used for exhibits of the League's work in response to requests from various organizations. Lists of officially approved material bearing the League's label, and lists of educational material and of reprints of papers prepared by the officers of the League and others are sent on request from the League's office, 1 Madison Avenue, New York City.

Our officers and other experts on the subject of posture have given illustrated lectures from time to time before educational and other organizations, and have published papers in which the

practical value of good posture was strongly emphasized. Our president has just returned from a trip to the Pacific Coast states, where she lectured before large audiences at the principal universities, and reports great enthusiasm and eagerness for information on this topic.

The League has an attractive posture pin which it awards for a certified standard of excellence in posture. It is conducting a prize poster contest in which high school students are invited to compete. This contest is nation wide, including Alaska, Canal Zone, Porto Rico, Hawaii, Philippine Islands, and our new possessions, the Virgin Islands. Two prizes of one hundred dollars each are offered, these being generously contributed to the League by interested members. The object of the contest is to stimulate interest in correct posture among high school students; to learn their reaction to their instruction in physical

The contrast is seen between the correct way of leaning backward and the slump sitting posture. Slouchiness of posture must be trained out of the recruit if he is to become efficient and able instantly to translate a command into action.

training; and to secure two choice posters appealing particularly to this class of students, these to be put into permanent form and listed in the League's educational material.

Take Tracings of Human Figure

The Mosher-Lesley Schematograph, a camera-like instrument used for making tracings of the outline of the human figure from a front, back or profile view, useful in securing a permanent record for study of postures and their effect, may be obtained through the League for use in posture work.

The League gives information to state and national boards and departments, and cooperates in health work with other philanthropic organizations such as the Young Men's Christian Association and the Anti-Tuberculosis League.

Standardize Commercial Products

When commercial use is made of material which has been officially approved on recommendation of one of its technical committees after examination, the use of the League's official label of approval on the goods is required. This is obtained at a very small cost and affixed to the material in order to protect the manufacturer, the League, and the public. By careful management this small income almost finances the very modest office expenses. No official receives a salary or shares in profits. What has so far been accomplished has been at a personal sacrifice by busy

The correct and incorrect way of leaning forward. Physical training solves only a part of our difficulties if habitual postures do not insure free play of lungs, heart, and abdominal organs.

professional experts. Much remains to be done to bring the level of our current knowledge and practice up to that of the average in most lines of ordinary supplies. Research is needed, especially into industrial conditions, and there should be an active propaganda to embody the best standards of clothing, seating, etc., in the commercial output. In order to accomplish what it hopes to and should accomplish, a larger membership, more active workers, and a greater financial backing are needed. The science and art of the matters that have the most direct bearing on our health and comfort are several generations behind the age. It is a new and neglected field, and one in which the medical and nursing professions are peculiarly interested. We make an urgent appeal to all to inform themselves of what is being done to better conditions, to apply ascertained principles in daily, school and industrial life, and in general to study existing conditions, and to cooperate in their improvement.

Great talent is shown by these boys at the Walter Reed Hospital in basket making. The work adapted to their needs shortens the tedium of convalescence and makes possible a more complete recovery.

SOCIAL PHASES OF HEART DISEASE IN CHILDREN*

By A. LEVINSON, Chicago

Tell me what a man thinks necessary in the care and training of children and I will tell you all about his ethics, says one of our leading psychologists. If society is to advance progressively it must be in the line of better children more carefully nurtured, and with fewer handicaps.

Intelligence in the pursuit of educational as well as health work demands that society look to the care of the great army of cardiac cases among children whose protection requires more than home care if their lives of tragic, ineffectual effort are to be transferred into spheres of comfort and usefulness. With activities within safe limits they suffer no hardship.

IN VIEW of the enormous number of children with heart disease invalided in children's hospitals, those incapacitated at home, and the many others who run around the street with unrecognized heart lesions it appears strange that so little is written on the social phase of this problem. The heart as the most vital organ, supplying, as it does, the blood to the rest of the body, should command more attention than it at present receives as to its social phases. Such tardy consideration, however, seems to be the fate of this royal organ, for, surprising as it may seem, the circulation of the blood was not known till 1628, when it was discovered by Harvey. One would think that this fundamental vital fact would have suggested itself to the first person who exerted his thinking power when dissecting a human body. Fortunately the medical aspect of heart disease has received quite an impetus of late through the research of Mackenzie, Lewis and many others. It is its social bearings, especially the social phase of heart disease in children, that calls for more attention.

Heart Lesions Preventable

With the exception of a negligible number of cases that are congenital, most cases of heart disease in children are the result of infection and can either be prevented or their hardship lessened. Usually heart disease in children is preceded by recurrent attacks of tonsillitis, very often accompanied also by rheumatism. We are far from advocating the idea that all tonsils in children must come out. The tonsils are in the throat for some purpose, most likely to ward off infection; but as soon as the tonsils become diseased they not only fail to perform their function, but become themselves disseminative of disease and under such conditions should be removed. The same is true of the teeth. They are in the mouth for the purpose of masticating food and helping the process of digestion. However, when decayed and infected, the teeth should be removed. These two correlations, the preservation of healthy tonsils and the removal of badly diseased ones, would prevent many cases of endocarditis in children.

Next to tonsillitis, endocarditis is often a sequence to some other acute infectious disease such as diphtheria, scarlet fever, or pneumonia. The best way to prevent development of endocarditis subsequent to an acute infectious disease is to keep the patient at rest after the subsidence of the disease for a sufficient time to avoid overworking the affected heart muscles.

Next to prevention of heart disease the most important thing is the early detection of its presence. Often when the endocarditis is still acute, a great deal can be done for the patient. The opportunity often presents itself to compare an acute endocarditis which has been treated properly with one which had not received treatment. There is now an unfortunate tendency in medical literature to minimize the importance of heart murmurs. This teaching, which may be justified in the adult patient, has its danger for the child. While often a murmur may indicate no organic changes, it shows the presence of some pathology, even though it may be functional. Unless steps are taken to investigate the type of murmur, a diagnosis of "merely functional" may be reached which is deleterious to the patient. Many a case of so-called functional murmurs has been known to result in generalized edema and all other manifestations of a decompensated heart.

Thorough Investigation Called for

All cases evincing heart murmurs, dyspnea on exertion, or cyanosis, should be thoroughly investigated, and treatment instituted. The question of the valve involved is of minor importance. In fact, it has been shown that in practically all heart cases in children more than one layer of heart tissue is affected; in other words, they are all carditis, instead of being endo-, myo-, or pericarditis.

*The eighth of a series of articles by Dr. Levinson on medicosociologic problems in the field of pediatrics presented in successive issues of Modern Medicine. The series constitutes practically a treatise on child welfare work.

The treatment for endocarditis may vary with the clinician. One phase of treatment, however, everybody agrees upon and that is rest. Whatever else is done for the child, or whether anything else is done, rest must be insisted upon. The rest must be complete for a time. Later, when the heart returns to its normal size, gradual exercise should be instituted. In this way many cases of acute endocarditis may return to normal condition and present no further problems.

How long the patient is to stay in bed is a question to be decided in each individual case, the determining factors being the size of the heart, the presence or absence of murmurs, and the general state of health of the patient. The patient's stay in bed should be made as interesting as possible. Such occupations as knitting and making baskets have been found quite entertaining to this type of patient. When the acute endocarditis has been too severe in character, or when no proper rest has been instituted and a chronic endocarditis has resulted, the patient becomes a lifelong problem, and must henceforth be regarded as an invalid.

Here again, not enough attention is being paid to the social phase of chronic heart cases. Here and there a cardiac clinic is established, and a paper on the subject is published, but such measures do not suffice. Each dispensary should have a children's cardiac department, and each health department should have a special officer to deal with the problems of cardiacs in the public schools.

Of the many problems confronting the mother and the social worker in connection with chronic heart cases, the following are probably the most important: (1) How to keep the patient from overexerting himself, and (2) how to teach the child some method of gaining a livelihood.

Even while in a hospital a child does not like to be an invalid, to rest in bed and do nothing, simply for the reason that his heart does not work well. A child is naturally too active to sit around idle. This problem is still more involved when the child is at home. However much it is explained to the child, he cannot get the proper viewpoint. The only way to keep a child at a minimum amount of work is to supply him with some work, such as cutting of papers, the making of baskets or other kinds of occupation that will keep him fairly quiet but still doing something. In the hospital, teachers of occupational therapy help a great deal in this regard. The home case requires the mother to play the part of the occupational therapist.

Vocational training is of even greater importance to a child with this handicap. A patient with chronic endocarditis is not able to do heavy work, but is, as a rule, able to do light work, unless the heart becomes decompensated. It is up to those who are interested in child welfare to teach a child with chronic heart disease some light occupation so as to make it possible for him to earn his living and at the same time avoid too great a stress upon the heart. Of course, not every case of heart disease is affected to the same degree, and it follows that an occupation that is proper for one case may be deleterious for another. Yet some general rules may be established in such cases and in addition to such safeguards each case should be examined frequently, and the occupation of that individual guided by the advice of an expert physician. Indeed, it might be advisable to have all cases of chronic heart disease registered in some heart bureau, where the patient could come from time to time for reexamination and for advice. Whatever the future work of the particular patient may be, it would be advantageous to institute the teaching of a trade or a profession early in life so as to enable the child to master the profession or trade by the time it becomes necessary for him to earn a livelihood.

Public Schools Serve Public Health

The question of schools for cardiacs is one that requires much thought. There is at present no uniformity of opinion as to whether or not a child with endocarditis should attend school. Some physicians advise every cardiac child to stay away from school so as to avoid overexertion; others allow the child to attend school as long as the heart is compensated. It is my belief that if the child is under supervision, attends school only part of the time, and does not walk many flights of stairs, no harm will be done to the heart. The ideal thing would be to have special schools for cardiac children which would make it possible for the teacher to pay close attention to the child, and in which the child would not be called upon to walk stairs.

The question of diet for cardiac children requires the closest attention. A disabled heart cannot furnish as much blood to the stomach and intestines as a sound heart and, as heavy food or large amounts of food require a greater blood supply to the digestive organs, it becomes important to regulate the diet of cardiac cases.

The urine of a cardiac should be examined at frequent intervals. If not watched closely, and at times, even if watched, the cardiac will develop an insufficiency of the kidneys. The blood vessels of the kidney are so dependent on the heart that, when the heart is affected, the kidneys suffer. The interrelation between the heart and blood ves-

sels has given rise to the term cardiovascular disease, a term broad enough to embrace the secondary changes arising from cardiac trouble. In order to keep informed of the vascular changes in the kidneys urinalysis should be done at frequent intervals. One of the best means of determining kidney function is to measure the twenty-four-hour output of urine and compare it with the fluid intake during the same twenty-four hours. The presence of albumin and casts naturally is of great importance.

It is not very easy to carry out these examinations with the patient at home. Both the patient and his parents often disregard the instruction. They get tired of coming to clinics with a bottle of urine for examination when nothing else is done for them, and it is here that the social worker can do her share. She can impress upon the patient and his parents the necessity of these examinations which may for a long time prove negative. She can impress upon the patient that it is his business to adhere to the régime outlined by the physician; otherwise, the tests will become positive and may prove a detriment to life.

Some cardiacs present problems aside from those relating to the heart proper. These are the patients whose endocarditis is coincident with some other complication, such as tuberculosis, or asthma. These cases require special medical and social care. At times they require to be sent away from home for their asthma, and still the heart may not stand the new climate. Such cases require a great deal of thought and attention, and it is only the conscientious physician and social worker who can alleviate the suffering of these little patients.

WHEN THE EYE-GATE IS CLOSED

DIVERSE reasons have been assigned for the neglect of certain urgent problems that have to do with public welfare, but an all inclusive explanation of the prevalent reluctance to consider them is that it is entirely a matter of attitudes, these matters being regarded as problems difficult of solution instead of as questions of vital interest open for investigation, and emotions get organized around them so that the investigations undertaken are approached with a strong personal bias for the result feared or desired.

International.

In the institute for Blind People, Amsterdam, Holland, children are instructed not only in the "livelihood arts," but are taught the elements of mathematical science by means of the ciphering board, and to read and write in the Braille system. Their mental training does not lag because one avenue of information is cut off.

International.

Through the aid of a blocked board similar to a large type box in which square blocks with raised dots are set or removed according to the operations involved, the elements of mathematical science are made clear to the blind. By such means the blind are made to "see" despite the loss of this important sense.

In the matter of education, for instance, it is popularly conceived that Johnny gets along well in school because he is "exceptionally bright," and that Mary is retarded because of slow mentality or of deficient capacity. The facts in the case may be the other way around; Johnny may be the duller, but better understood and more intelligently handled according to the lines of his natural predilections; or in the case of Mary, there may be closed one or more of the avenues of sense impression so that she does not apprehend what is expected of her. Only in-

telligence quotients scientifically arrived at will serve to indicate whether any two cases are parallel, if indeed they are at all comparable.

Our whole idea of what constitutes the phenomenal world must be gained through the avenues of the senses. Sense perceived objects are popularly thought of as consisting of matter. Our notions of natural phenomena, ponderosity, hardness, impermeability, configuration, motion, color, warmth, and the rest, must be gained through muscular or pressure sensibility, or through the faculty of vision. Such mental abstractions as may afterward develop, grow out of the organization of such perceptions, and their extent and verity ultimately depend upon the integrity of the senses, and of their special training.

There is nothing in the popular notion that the blind are beneficently endowed with some sort of a sixth sense

International.

Though deprived of the sense of sight, this boy is gaining a knowledge of the principles of geography and the formation of the world's surface through the touchstone of a raised map.

to compensate for their loss of vision. A child blind from birth is retarded mentally to the degree that his handicap is not overcome by special training and by carefully adapted apparatus to provide substitute means of communication. The popular commiseration for the state of the blind which gives him charity instead of the requisite training, or which seeks to do everything for him instead of bringing out his own powers of self-help, thus forcing upon him a "place in a corner out of reach of all danger like a feeble old man or a child in swaddling clothes," must give way to the conception of these handicapped as normal human beings minus one sense, who are entitled to a training adapted to their needs which will open to them every possible avenue of communication.

International.

This picture, taken at the Institute for Blind People at Amsterdam, Holland, shows the special writing machine on which the blind pupils learn to prick the "Braille" letters in the paper.

The "poor dear" treatment never got the blinded soldiers out of their difficulties. Their problem was primarily psychic. Their fund of knowledge was normally organized on a sight basis. Once the first psychic depression was overcome, they were less handicapped than they had thought, and their period of adaptation was remarkably shortened by re-education. In these cases and in the case of the industrially blinded the problem is largely vocational re-education, but the blind child without special sense education, reduced to organizing his knowledge on a sightless basis, suffers a mental handicap and needs education not only to earn a living, but to learn how to live. S. P. M.

THE INDUSTRIAL MEDICAL OFFICER

In an address on industrial medicine recently, Dr. S. Dana Hubbard states the problem of the medical officer of the plant:

Medical aid almost specifically concerns industry. It is not sufficient simply to have a dispensary in the plant with hours for advising or treating such employees as may from time to time need medical advice, or to have first aid applied. Industrial medicine demands not only a knowledge of the human body, a knowledge of the conditions which impair it, as well as the means for restoration when impaired, but also the more necessary measures that will enable workmen to reach and maintain their greatest capacities for good work. The ability of medical officers to participate in this plan establishes the logical relation of medicine to industry.

Since the value of medical service will be measured by its effect on production, the most useful industrial medical departments are those best able to avoid accident and prevent absence incident to illness which means, loss of time, unnecessary expense to both management and worker, as well as increased labor turnover, diminished production, and in frequent instances waste of material. The human element must be known and evaluated. The long way is the safe way, but it is the short way which usually is taken and is the dangerous way because human nature loves to take a chance. Managements and labor both seem today to object to the long way. If time is so essential a factor that the long way must be sacrificed, how can labor be speeded up without actually occasioning a breakdown or heating up of the human mechanism?

THE AMERICAN JOURNAL OF OBSTETRICS AND GYNECOLOGY

WE have just received the first copy of a new medical publication, the *American Journal of Obstetrics and Gynecology*. For some time past there has been no journal exclusively devoted to this highly important branch of medicine in this country, where gynecology had its birth and obstetrics made some of its most notable advances; and yet, such special journals are indispensable for the focalization and progress of their respective specialties. We, therefore, welcome warmly our new contemporary in our midst. English speaking physicians all over the world who are interested in this field will hail the advent of this journal. It is, at the present time, the only one of its kind in the English language.

It is safe, then, to predict a brilliant future for the new enterprise. A large editorial board represents the leading specialists on this continent who, we are told in the foreword, are taking an active part in the management of the journal. The editorship is in the hands of Dr. G. W. Kosmak, of New York, a man whose great experience both as a medical editor and as a clinician and teacher renders him pre-eminently suited for his distinguished position. The department of reviews and abstracts is in charge of Dr. Hugo Ehrenfest of St. Louis, and this part of the journal, as it appears in the issue before us, promises to be one of the very strong attractions of the publication.

This first copy makes the best possible impression. The papers published are of the very highest type, establishing at once an elevated standard. Illustrations are numerous and good, and the entire make-up of the journal is pleasing and dignified. The C. V. Mosby Company of St. Louis, as publishers of the new journal, are to be congratulated on its energy, and its willingness to serve the interests of science and the needs of the medical profession.

THE SO-CALLED ENDOTHELIOMA

MALLORY[1] has made a very excellent and extremely detailed study of the cytology of "the so-called dural endothelioma," as well as of the "perineural fibroma" of the central and peripheral nerves. He has used special stains for determining the nature of these cells, and he is an authority on staining reactions of cells.

It is unfortunate that the common tumor of the dura, which is the one studied by Mallory, is almost universally called *dural endothelioma*. These tumors cannot properly be given this name, since, as Mallory points out in his first conclusion, the dura is not lined by endothelium. MacCallum[2] also makes this point clear in his "Textbook of Pathology."

The erroneous terminology in calling this tumor endothelioma is only one of a long list in which pathologists have given names to tumors, regardless of their histological origin.

Mallory has made clear in his study that "so-called dural endotheliomas arise from the lining layer of the arachnoid." These arachnoid cells arise early in embryonic life from the mesenchyma, and belong to connective tissue type of cells. When these cells proliferate, they first give rise to fibroblasts. Mallory has demonstrated that the tumor under discussion is fibroblastic in origin and that it arises from the arachnoid. He suggests the

1. Mallory, F. B.: The Type Cell of the So-Called Dural Endothelioma. Jour Med. Research, 1920, xli, 349.
2. MacCallum, W. G.: A Textbook of Pathology, 1918. Author please complete reference.

name *arachnoid fibroblastoma*. It has characteristics which are different from fibromas—or fibroblastomas—found elsewhere, such as peculiar whorl-like formations, sometimes producing pearl-like structures, etc. The tumors arising from the perineurium and endoneurium are likewise different from the usual type of fibroma, and have been known as neurofibroma, false neuroma, fibroneuroma, and Von Reclinghausen's disease. These tumors also differ from the arachnoid fibroblastoma and from the common types of fibroma. The term suggested for this tumor is *perineural fibroblastoma*.

The common tumor of the nervous acusticus and other central nerves is a perineural fibroblastoma. It is important to note that this is a different type of tumor than the arachnoid fibroblastoma.

One important practical point brought out by Mallory is that whereas the arachnoid fibroblastoma can invade the dura, skull, and soft parts outside, it cannot pass through the arachnoid and invade the brain. This is believed to be because it has risen from the arachnoid.

Attention is here called, therefore, not only to the proper terminology of these tumors, but also their cytological structure and origin, as this is important for the proper conception of the nature of these tumors.

Attention may properly be called at this place to the following erroneous names for tumors: *Perithelioma* cannot be considered a correct name, since there is no structure which it is proper to call *perithelium*. "So-called endothelioma" of the peritoneal cavity, pericardium, and pleura, is an erroneous name, since these cavities are not lined by endothelium, but are lined by mesothelium. These last mentioned tumors can more properly be considered as epitheliomas, and certainly behave as such.

W. T.

POST OPERATIVE PULMONARY COMPLICATIONS

"POSTOPERATIVE pulmonary complications constitute a serious menace to any patient who submits to operation. Reliable statistics show that one patient in every thirty to fifty patients operated on, no matter what the anesthetic, develops a pulmonary complication, and one patient in every 150 to 175 patients dies from some such complication."

This statement taken from an article by Elliott C. Cuttler and Alice M. Hunt[1] is highly significant. Such a postoperative mortality, from a single set of complications, is appalling, even when it is considered that in the majority of cases a bronchopneumonia may mark the terminal stage of any *exitus fatale*.

Reviewing their article: The authors report 1,562 patients actually submitted to surgical operations under anesthesia, 55 of the series developing a definite postoperative pulmonary complication, fatal in eleven cases.

A combined report of the Mayo Clinic of 1910, 1912, 1913, Montreal General Hospital, Massachusetts General Hospital, and the Peter Bent Brigham Hospital showed the astounding fact that about 2 per cent of all patients developed a postoperative pulmonary complication, with a mortality of 25.2 per cent; or, that approximately one patient in every 185 operated upon died as a result of this complication.

Pulmonary complications occur most frequently after operations involving the epigastrium. In their first study the authors found a morbidity incidence in operations in the upper abdomen of 7.7 per cent. In the series under consideration the incidence was 8 per cent, and they quote Laewen as reporting a morbidity of 8.1 per cent following epigastric operations.

During the colder months of the year pulmonary complications were more frequent, a finding which confirms the observations of Whipple, Armstrong, and others.

The anesthetic is not the chief factor in producing the pulmonary complication but plays a very minor rôle. "Ether pneumonia" is an unfortunate misnomer. They quote Henle, Gottstein, and v. Mikulicz as reporting more pulmonary complications following local than following general anesthesia. The morbidity percentage at the Peter Bent Brigham Hospital following ether was 3.39, gas-oxygen 4.24, local 1.63 per cent. However, it is to be remembered that the poor risks were given gas or local. The rôle played by sepsis is shown by the fact that all fatalities occurred either in patients who were operated upon primarily for inflammatory lesion or in whom the site of operation, being in an unclean field, such as intestinal operations, might readily favor the occurrence of sepsis.

In analyzing the pulmonary complications the various clinical entities are discussed.

Lobar pneumonia played an unimportant part. Only 4 cases, or 7 per cent, of the pulmonary complications fell into that classification, and in this group there were no deaths. Nitrous oxid and oxygen was given in one of these cases, ether in the others.

Bronchopneumonia comprised the largest group of all of the postoperative pulmonary complications—21 of the 55 cases—and 8 of the 11 deaths of the total 1,562 operations could be ascribed to its occurrence. The authors admit the danger of being misled, because "the majority of old people at necropsy show some terminal bronchopneumonic process," but add that "we have tried not to include in this group patients who have died with a bronchopneumonia, where we felt that the bronchopneumonia was not the really important factor." The patients in whom bronchopneumonia did develop were on the whole poor risks. More than half of them were at least fifty years old and had at the time of operation either some pathological lung findings or were septic. Trendelenburg position may be blamed in a few instances. In most cases the complication was probably caused either by direct extension of the infection, or by emboli thrown off during epigastric manipulations.

Bronchitis caused 30 per cent of the pulmonary complications, but no deaths. About one-third of the bronchitis cases followed herniotomies, which may be accounted for by the emboli being thrown into the venous circulation by injury to the delicate pampinoform plexus. Pleurisy causes less than 4 per cent of the pulmonary complications and lung abscess occurred but twice. Empyema occurred only once and that time following an operation on the pleura itself. Pulmonary embolism occurred three times with two fatalities.

The authors lay stress on the fact that following operations where the chest is splinted either by tight dressings or by the patient himself through voluntary and involuntary efforts to avoid pain which might follow more ample respiratory motions, the incidence of pulmonary complications increased, probably due to the resulting hypostatic condition.

The authors believe that embolism is the chief cause of pulmonary complications. They do not believe irritation caused by the anesthetic to be an important factor except in those cases presenting evidences of pulmonary lesion before the operation. They point to the morbidity

1. Cuttler, Elliott C., and Hunt, Alice M.: Post-Operative Complications, Arch. Surg., 1920, I, No. 1, pp. 114.

rate following local anesthesia. They believe the danger of sepsis lies in embolism. In discussing the embolic theory they say: "The men considered as gentle, slow operators have a proportionately lower morbidity, which we consider to be an added reason for the embolic theory. These men, though subjecting their patients to a longer operation, cause less trauma and therefore less embolism."

In the summary the article concludes that "embolism from the operative field is the chief factor in the etiology of pulmonary complications. It is favored by sepsis, trauma, and the mobility (immobility [?] Ed.*) of the part. Other factors of varying importance are pre-existing lung disease, irritation of the anesthetic, and such general factors as old age, chilling, and poor general condition." The following prophylactic measures are suggested: (1) A reduction in operative trauma in an effort to produce as few and small thrombi as possible (2) every effort in septic cases to prevent further extension of infection. . . . (3) The avoidance, if possible, of operating on patients with an existing lung lesion, however slight; (4) avoidance of chilling both by cold packs in laparotomies or by widely gaping wounds and by exposure after operation; and (5) making each case before operation as good a risk as that case can be made.

The assertions and statistics of the paper in question are startling, to say the least. Most of us have been under the impression, especially of late, that the average operative mortality was low and that the mortality from pulmonary complications was much lower.

In order to quote definite statistics from standards works we searched through many of the recent publications. The conclusion arrived at is that there is an urgent need for reports from various institutions regarding their postoperative mortality. Practically all the authors cite the same references as those quoted by Cuttler and Hunt, such as Bibergiel, Whipple, v. Mikulicz, Henle, Lexer, and Wolff, but make no allusions to more recent publications. Brunn[2] reports 56,233 ether anesthetics with eleven deaths. He does not state whether this is a total postoperative mortality, an immediate mortality, or a mortality due solely to the anesthetic, but we surmise that this last is what he means. O. F. McKittrick[3] says, in speaking of postoperative pneumonia: "the percentage is very small, ranging from 0.04 per cent, as reported by Beckman, to 2.2 per cent, as reported by Whipple," but, further, "these figures are considered low and probably do not present the true incidence of the condition." He quotes Bancroft and Beckman as saying that septic emboli cause many of these conditions. McKittrick adds one very plausible cause for the incidence, namely, that in most hospitals the former habits of the surgical patient are disregarded and he is given a night gown of light weight, open in the back, a certain amount of covering, regardless of whether he is accustomed to heavy woolen pajamas and many blankets or scarcely any covering at all.

Joslin and Gage (4) noted that at Camp Devens in a series of 1,423 operations pneumonia developed in 2.1 per cent; 75 per cent of these followed abdominal operations. They claim this high incidence was due to prolonged anesthesia rather than to the actual site of operation. They add: "Our observations would seem to us to indicate that these postoperative pneumonias are really inhalation pneumonias and that the administration of the anesthetic, the exposure of the patient to cold and wet during the operation, the care until full consciousness is restored, are the important factors to be considered in studying the means of prevention."

We hope that others reading the article of Cuttler and Hunt will be startled as we were, and that those who are in a position to do so will realize the urgency of reporting statistics from their various clinics and hospitals. We would recommend that all the large, accredited hospitals report the following statistics: (1) Total number of cases operated and type of operation. (2) Total postoperative mortality. (3) Percentage of this mortality due to lung complications, other complications, etc. To ascertain the percentage of postoperative pulmonary morbidity is a task which demands the careful and painstaking work which Cuttler and Hunt have devoted in preparing their article.

If it is true that one patient of every 150 to 175 operated upon in the average city hospital dies, not as a result of his original disease, not as a result of shock, hemorrhage, or other operative complications—which at times seem unavoidable—but as the result of a complication which had nothing to do with the previous illness, and which might be favorably modified by certain precautions, we ought to realize it. If such a specter exists, the surgeon ought to be fully aware of it and bear it in mind in giving a prognosis. If it is true that one out of every 150 to 175 cases operated upon dies from pulmonary complications, the surgeon must frankly throw this objection into the balance when weighing the disadvantages against the advantages in so-called elective operations.

*Editor's note.

RAPID METHODS OF PNEUMONIA TYPING

IN EVERY case of pneumonia, whether it is one of classical lobar pneumonia or one of the peculiar kinds of pneumonia which have been occurring in recent years, the type of Pneumococcus which causes the infection should be determined. Whereas the clinical results of administration of Type 1 Antipneumococcus serum in cases infected with Type 1 are not absolutely clear cut, nevertheless sufficient has been accomplished with this serum for its use to be continued. It is unfortunate that there is no satisfactory serum for types of Pneumococci other than Type 1. The Antipneumococcus serum of Kyes is a polyvalent serum and some favorable reports of its use are in the literature. The supply of this serum, however, is limited and it is not yet available for general use. The only available serum is the Antipneumococcus Type 1 serum and this can be used only for Type 1 Pneumococcus infections.

The original methods[1] for typing Pneumococci take quite a number of hours for their completion. Although the technic is not very difficult, it contains many pitfalls, and in all probability many of the poor results reported from use of Type 1 Antipneumococcus serum can be attributed to erroneous typing of the Pneumococci. A number of simpler methods have been devised but some of these also take a comparatively long time to do.

The most recent rapid method reported is that devised by Oliver.[2] He utilizes the fact that Pneumococci are soluble in bile and he places pneumonia sputum and bile together in a test tube. After solution of the Pneumococci has occurred, which takes place almost immediately, this mixture is brought in contact in separate test tubes

1. Litchfield, Lawrence: Pneumococcus Meningitis—Treatment by a Specific Antipneumococcus Serum, Jour. Am. Med. Assn., May 10, 1919, lxxii, 1345.

with the three types of Antipneumococcus serum. He states that a precipitin reaction occurs in a very short while, always within a half hour. This reaction takes place best with a specimen containing Type 1 Pneumococci. Oliver has controlled his work with the standard methods and, whenever he could determine the type with his method, it could be verified by the other methods. When he could not determine the type, the other methods always showed either a Type 4 Pneumococcus, or a Streptococcus, for neither of which is a therapeutic serum available. Two things recommend this test, it is simple and it is rapid. It should be tried out in various laboratories in the hopes that Oliver's results will be verified. If with this method a Type 1 Pneumococcus infection could be determined within a half hour, it would be a great satisfaction in the very sick patients to be able to administer Type 1 Antipneumococcus serum, since the older and longer methods of Pneumococcus typing consume too much time to be of any benefit to the patient.

In typing pneumococci attention should be called to another method in which the blood of the patient is used, and, therefore, sputum—which is sometimes difficult to obtain—is not necessary. This method in the hands of Loewe,[3] who devised it, has given consistent results. It is, therefore, important that this method should also be tested at other places. The advantage of this method is that in cases in which no sputum is available, and when it is not desirable to perform a lung puncture to secure some of the pneumonic exudate, the patient's blood can be used to determine the type of pneumonia. While this method takes less time than the older methods, it is not as short as the one described by Oliver. W. T.

THE TOXIC STATE OF MENSTRUATION

THE "Studies in the Psychology of Sex" by Havelock Ellis contain as an appendix to one of the six volumes a most interesting essay entitled "The Influence of Menstruation on the Position of Woman." In it Ellis discusses the belief, prevalent in the past and still at the present time among primitive and civilized peoples in widely different parts of the world, that woman is "unclean" during menstruation. She is supposed to paralyze social activities, being possessed by evil spirits; and to destroy the powers of life, causing flowers to fade, fruits to fall from the trees, grains to lose their germinative power, and grafts to die. All this is summed up in those old lines:

Oh! menstruating woman thou'rt a fiend,
From whom all nature should be closely screened.

A former belief also in beneficial powers exerted by her, such as those of a prophetess or as protectress of the orchard against caterpillars, as mentioned by Pliny, in our own time seems to have disappeared. A widespread faith in her pernicious influence alone survives. It still can be easily traced in practical and commercial—and even medical quarters. In the great sugar factories of northern France the regulations strictly forbid a menstruating woman to enter the factory while the sugar is boiling or cooling. To turn to the East:—in the opium factories of Saigon no woman is employed, because her presence during menstruation would cause the opium to become bitter. As recently as 1878, a lively correspondence was carried on in the *British Medical Journal* in response to the question of a physician whether it is true that hams would be spoiled if cured by women during menstruation. One physician expressed his surprise at such a discussion, since he thought that this fact was well known to every housewife; and one physician facetiously inquired, if this is so, what happens to the patients of a menstruating lady doctor? Ellis ascribes to the persisting influence of old primitive ideas the dread of some surgeons and gynecologists to operate on menstruating women. He considers such an attitude a tissue of phenomena, inextricably woven, of folk lore, autosuggestion, false observation, and real mental and nervous anomalies incident to menstruation. In an advanced civilization these ideas of a special and mysterious connection between the menstruating woman and the occult forces of magic tend to die out. Ellis closes his most instructive essay with the following sentence: "Menstruation is no longer a monstriferous state requiring spiritual taboo, but is a normal physiological process, not without its psychic influences on the woman herself and those who live with her."

Every modernly trained physician will readily subscribe to this opinion—if he has not run across an article, quite recently published in the *Wiener klinische Wochenschrift*[1] by the well known pediatrician, Professor B. Schick of Vienna.

A young woman, employed in his office, by his orders placed a bunch of fresh and beautiful roses in a vase. The next morning they were withered and dead. He suspected neglect on the part of the girl, but she confessed that she quite expected this to happen, because all flowers die which she touches during the time of her menstruation. Schick, thoroughly familiar with the many superstitious beliefs concerning menstruation, decided to investigate this matter, and proceeded entirely in accord with the approved methods of exact and scientific investigation. He made control observations, recorded the duration of touch, prevented direct touch by means of rubber gloves, added circulating blood, menstrual blood, also sweat of menstruating and non-menstruating women in varying quantities to the water in which flowers were kept, ascertained difference in the effect of yeast on rising dough manipulated by menstruating and non-menstruating women, etc., etc. Those interested in this study—to our best knowledge the first scientifically correct study of an assumed toxic influence of the menstruating woman—are referred to the original article for further details. These investigations are not as yet completed, but Schick already feels fully justified in asserting that at the time of menstruation a toxic substance is formed in the organism which exerts a distinct deleterious effect on blooming flowers, and, less markedly, affects yeast cells. This toxin circulates, probably within the red cells, through the blood stream. It is excreted by the sweat glands and with the menstrual blood. Its noxious effect is evident during the duration of the menstrual flow, though possibly at its very beginning and end this toxin exerts an actually stimulating effect on flowers and yeast growth. Different individuals show this phenomenon of toxicity in varying degrees. In some it seems permanently absent; but in those who exert this effect its presence can be established in every menstruation. Schick suggests that this latter fact, if finally confirmed, might possibly be found to have some relation to the symptomatology of menstruation in the individual patient.

This interesting article, written by a recognized medical authority, is worthy of serious consideration. It cannot fail to stimulate widespread and thorough investigation

of this problem. The near future undoubtedly will bring us many enlightening contributions and possibly a satisfactory explanation for that ancient but unshaken belief of the laity that menstruation is some sort of a cleansing process in which woman rids herself of poisonous matters.

STUDIES IN CHOREA MINOR—A COLLECTIVE ABSTRACT

By PARK J. WHITE, JR., M.D., St. Louis, Mo.

THE literature on the subject of chorea minor since 1910 represents a large amount of work and a small amount of progress—a record with which medical investigators are thoroughly familiar. About two hundred and fifty articles have been written on the Sydenham type alone; and, though only very few ideas have been advanced, these have brought forth such quantities of arguments for and against, proving and disproving, that the lack of results has by no means brought about a corresponding lack of literature. Consequently, a review which presents these few debated views on chorea and its treatment, omitting many of the pros and cons, would come nearer to meeting present indications than would an exhaustive study of all that has been written in the past decade.

That the disease occurs usually between the ages of five and fifteen, that it is more frequently met with in female children, that more cases occur in the Spring, that it is rare in negroes, all seem to be fairly well settled etiologic points. Concerning heredity, the fact that the form of chorea in which heredity plays an important part (Huntington's) is manifested in later life and gives a bad prognosis, and that the form in which heredity is unimportant is manifested in early life and gives a good prognosis, has called forth some comment.

Following a report of chorea occurring in seven members of the same family, the family history being negative for rheumatism, Burr[1] says, of chorea minor, that there is something which in very rare instances continues to act in families over several generations and shows itself by the occurrence of St. Vitus's dance, and that in such cases the disease may be regarded as hereditary. In the majority of children such an influence is absent, and heredity plays no part.

Pregnancy, according to McCarthy,[2] is one of the most important, if not the most important factor in the production of chorea in adult life. Evidence is lacking to show that this factor increases the susceptibility of the offspring.

A great many observers have stressed the importance of psychic causes in the production of chorea. To cite a few of the most recent opinon on this point—Griffith[3] says: "The direct effect of psychic causes is very decided. Often chorea develops promptly after such influences as fright, sudden grief, fear, and the like. . . . Imitation is an occasional psychic factor."

Discussing a paper by Strauss, Haberman[4] mentioned that many cases had come to Starr's clinic which should be classed as psychic chorea and which were cured by hypnosis.

With regard to the neglected subject of recurrences, Tilney[5] remarks: "So many times we get these cases well, then they go back to their homes and, later, are either brought to us or come with a recurrence. . . . There is a possibility that something in the home environment, the social environment, is important."

Local increases in prevalence of the disease have been noted, in rare instances amounting almost to epidemics. Opinions differ as to whether these outbreaks are of psychic or bacterial origin. The recent development of the latter theory will be considered later.

Pathogenesis of the Disease

It was not until 1884 that the bacteriology of the Streptococcus was put upon a scientific basis by the work of Fehleisen and Rosenbach. As early as 1889, Wassermann and Westphal suggested that the Streptococcus was the etiologic factor in chorea. The more recent bacteriological discussion of chorea has for the most part centered on the ability or inability of observers to isolate some form of this organism from the blood or spinal liquid or brain of cases of chorea.

Gordon,[6] in 1910, considering the evidence then at hand, came to the conclusion that chorea is an infectious disease, though he did not make a definite statement as to the exact nature of the organism involved.

An excellent review of the bacteriology of chorea is presented by Quigley.[7] He notes that many investigators have obtained bacteria in blood cultures in chorea before and after death, but that in a large number of these cases rheumatic fever or acute cardiac involvement was associated. Certainly but few attempts have been made to select uncomplicated cases of chorea for bacteriological study.

Among several observers quoted as failing to find any bacteria as a result of their studies, Quigley mentions Bartley,[8] Koplik,[9] Morse and Floyd[10] and others. He also mentions the researches of Poynton and Payne, whose work has caused so much comment that we shall consider it further. In their book entitled "Researches on Rheumatism," published in 1914, these authors[11] say, 'Chorea, one of the most remarkable of all the clinical phenomena, becomes at least more comprehensible when we find that in the same patient a micrococcus isolated from an acute rheumatic pericarditis may also be discovered in the pia mater and brain; and further that, when inoculated intravenously into animals, it may also be found in these situations producing irregular involuntary movements by virtue of tissue changes that result."

They regard chorea in the rheumatic as a symptom of rheumatic infection, due to the Diplococcus rheumaticus which they have described.[12] Prior to 1910, and many

writers later have called attention to the association of chorea and rheumatism. Kerley,[13] for instance, states that more than 50 per cent of his cases have been rheumatic at some time or other; and that this figure would be raised to 80 per cent if the family history were to be taken into account.

Holt and Howland[14] say that there is a very close connection between chorea and rheumatism, adding that there are other cases in which the rheumatic element cannot be found.

Griffith[15] believes that there is much to support the theory of infection, but maintains that definite proof that rheumatism itself is due to a microorganism is still lacking. This brings us back to the fact that the claims made for their Diplococcus by Poynton and Payne need only consistent verification by other workers to be accepted. To date this verification is still lacking. Again, the figures on relationship between rheumatism and chorea depend largely upon what is meant by the term rheumatism. The more inclusive the definition, *i. e.*, including afebrile "growing pains," the greater will be the evidence of relationship.

History of Previous Infections

In an article on the autoserum treatment of chorea, Brown, Smith, and Phillips[16] say: "There are many who believe that chorea is always a manifestation of infection, that rheumatic fever is the commonest infection which produces the manfestations; but that other infections may sometimes produce the disease. This view would explain the cases which have occasionally been observed to follow such other infections as scarlet fever. It is interesting to note that the other diseases with which chorea has been associated are conditions in which Streptococci are frequently found." They quote Loubet's opinion that the lesion is a mild encephalitis caused by the toxin absorbed from an infection.

In a study of 300 cases of chorea, Fraser[17] obtained a history of previous rheumatism in 53 per cent. There were 115 patients who had never had rheumatism, and of these 25 per cent developed it within six years. In Fraser's opinion chorea is merely a cerebral manifestation of rheumatism.

In 1916 Abt and Levinson[18] reported a series of 226 cases. They assert their belief in the relationship of chorea and rheumatism; but this particular series did not confirm their belief. Moreover, tonsillitis or other focal infection did not prove to be a prominent factor. Thirty-five recurrences were noted; one patient had four, four had three, and twenty had two recurrences.

There is, of course, no lack of literature incriminating "septic foci," such as the teeth and tonsils, in the causation of chorea. Brown, Smith, and Phillips[16] say that these foci have been in many instances the undoubted source of the infection, but that the eradication of the foci often fails to effect a cure of the chorea. Three cases reported by Daniel and Lambright[19] all showed marked improvement after tonsillectomy and dental care.

Tarr,[20] on the other hand, remarks that although hundreds of cultures have been taken from the blood, teeth, and tonsils in patients with chorea, nothing definite has been proved. Abt and Levinson[18] do not consider tonsillitis an important etiologic factor. King,[21] however, feels so strongly on the subject that in an article on "The Duty of the State to the Choreic Child" he urges that, inasmuch as most municipalities have school inspection, it should be their duty to warn parents of children whose tonsils and teeth are diseased of the liability to chorea and the possibility of endocarditis. The state, he says, should insist that all infections should be properly treated.

It is clear from the above that "focal infections" offer ample forensic opportunities to students of chorea as well as to those of other diseases.

Cultures from Spinal Liquid

The twenty-one cases carefully selected and studied by Quigley[7] should be considered in the light of his findings on examination of the spinal liquid in these cases. Such a study is particularly desirable in order to take a rational attitude toward the various intraspinal treatments to be discussed later. Ten of his cases yielded positive cultures from both the blood and spinal liquid, and fourteen in either one or the other. Six of the bacterial strains isolated from the tonsil, eight from the spinal liquid, and nine from the blood, were identical in their morphological and cultural characteristics. The organisms were short-chain Streptococci, two strains of which produced green and were apparently the same as the two isolated from a large series by La Fetra.[22] Of his organism Quigley says that it resembles the Streptococci, "especially the Streptococci or Diplococci frequently found in rheumatic fever and endocarditis,"—which sounds like a tentative agreement with the findings of Poynton and Payne. With these bacteriologic results we should expect to find cellular and chemical changes in the spinal liquid; but the cell counts and globulin tests in these cases gave quite negative results. The author is led to conclude that there are no changes in the meninges in chorea, as a rule. Leopold and Bernhard,[23] studying the chemistry of the spinal liquid of twenty-one cases of chorea in children, found no essential deviation from the normal. Richardière *et al.* reported lymphocytosis.[24]

Of the organisms other than the Streptococcus which have been held to be the cause of chorea, the only one which has been discussed at great length is the Treponema Pallida. It is noteworthy that a relationship between syphilis and chorea was not suspected until 1912, when both salvarsan and the Wassermann reaction had worked their way to general use and favor. The chief exponent of syphilis as the causative agent in chorea was Milian,[25] whose first paper appeared in 1912. At intervals since then this author has published numerous case records in support of his position. It was the success of arsenic in the treatment of both diseases that first led Milian to suspect the luetic nature of chorea. Arsenic has been used in the treatment of chorea since 1780 (Alexander). Salvarsan appeared in 1910; and within a year it was being used successfully in chorea by v. Bokay.[26]

Milian has apparently put all his emphasis on the therapeutic test. In 1919[27] he reported consistent success from

the use of mercury. In one case this was followed by a typical Herxheimer reaction, which in his opinion was diagnostic of syphilis.

The work of many other observers has shown quite conclusively that the relation between chorea and syphilis is merely coincidental. Even Milian, in the paper just quoted, said that he does not claim that all cases of chorea are of syphilitic origin, adding that all the subacute infections are capable of producing choreiform states. He insists, however, that specific treatment be tried in all cases.

Quigley,[7] Abt and Levinson,[18] and, particularly, Koplik,[28] have come out strongly against the luetic etiology. Making a special study of this phase of the subject, Koplik observed eleven cases of chorea in children from six to thirteen years old. He found cardiac involvement in five, rheumatic history in three, and evidence of lues in none. He has found no evidence that any of his cases of hereditary lues are particularly susceptible to chorea; and, finally, he says salvarsan does not cause such striking improvement as to warrant a continuance of its use.

Studies in the anatomical pathology of uncomplicated cases of chorea minor have produced no definite results. The emboli reported by some authors McCarthy[2] believes to be due to the complicating endocarditis in practically every case. Poynton and Payne[11] described a case with engorgement of the cerebral vessels, subpial hemorrhages, thrombosis, perivascular infiltration, and edema; also, the Poynton and Payne Diplococci. This case, however, was complicated by pericarditis and endocarditis.

These authors have advanced the theory that in chorea the nerve cells undergo hyperactivity, followed by weakening. With this theory Mayer and Mayer[29] agree.

Hematology in Chorea

With regard to hematology, eosinophilia has been repeatedly found. Leopold[30] studied twenty cases, with distinct eosinophilia in ten. There were nine cases with recurring attacks, and eosinophilia was present in six of the nine. He quotes Brown[31] and Cabot[32] as noting eosinophilia in uncomplicated chorea.

Among the complications more recently noted are gangrene of the fingers (Chodak[33]), peliosis rheumatica,[34] and muscular weakness. The last named should perhaps be considered an essential part of the disease rather than a complication, judging from the electro-myographic study of chorea made by Cobb.[35] He concluded that in chorea the inability of the muscles to maintain voluntary contraction is clearly shown in the electromyograms; and that weakness of muscular contraction is shown electromyographically by the lessened electrical discharge.

A Survey of Clinical Signs

As Langley Porter[36] says, "the clinical picture of chorea has never been more succinctly drawn than it was by Sydenham."

Two signs have recently been described which might be of aid in clearing up doubtful cases: namely, the voice sign of Swift[37] and the "handshake sign" of Heiman.[38] The former is elicited by having the patient pronounce "a" as in "are," making the sound steadily and evenly for ten or fifteen seconds. Changes in pitch and intensity are characteristic of the typical choreic voice.

To elicit the latter sign, the palm of the patient's left hand is placed upon the palmar surface of the observer's right hand. Then the thumb of the patient is embraced by the middle and index fingers of the physician, and the other four fingers firmly grasped by the remaining fingers of the examiner. The right hand of the patient is similarly grasped by the left hand of the physician. The attention of the patient is then invited by asking him a simple question. If the patient has chorea the twitchings of the hands will be distinctly augmented each time the attention is engaged. Heiman says this sign is often present when the characteristic twitchings are absent.

Therapeutic Measures Employed

Like so many other self-limited diseases about which little is known, chorea has a long list of therapeutic measures to its credit, each with a gratifying record of good results. Mental and physical rest, with particular attention to the exclusion of exciting influences, proper care, diet, nursing, and isolation, are standard methods of treatment in this disease, whose value is beyond dispute.

Arsenic, as we have seen, has been in use long enough to have attained a high degree of respectability. The last ten years have witnessed radical changes in the methods of its administration. In 1910 Hassin and Hershfield[39] modified the enormous doses of the drug given by Comby and Filatov, though continuing to give it in the form used by these authors, namely, as 1:1,000 solution of arsenious acid. McCarthy[2] advises against the use of arsenic in large doses, and says it should never be given until the physiologic limit is reached. He adds that salvarsan, intravenously, intramuscularly, and intraspinally, has given uniformly good results.

Bastedo[40] also opposes pushing arsenic to the "toxic limit," and recommends salvarsan when other means fail. Abt and Levinson[18] were not enthusiastic about their results with arsenic.

Sedatives, of course, occupy a prominent place in the treatment of chorea. Bastedo, who used bromides in doses ranging from thirty to 180 grains a day, got only mild suppression of the nervous manifestations. He calls attention to the fact that in chorea the trouble is not overtone but undertone, which is interesting in comparison with Cobb's results previously cited. He thinks that some other method which would not augment the lowering of muscle tone might be preferable to the use of bromides. This writer also opposes the use of chloral except in very mild doses,—mentioning one patient who got 120 grains a day without relief of choreiform disturbance—except death which came not long afterward.

Magnesium sulphate hypodermatically has received favorable mention by Heiman (1916), Acuna, Bastedo (1919), Cavalieri and others.

In 1910 Roden[41] obtained excellent results by treating a girl of ten with thyroid extract,—after arsenic, potassium iodid, potassium bromid, and brine baths proved unavailing. Goodman[42] quotes Hanneborg's success with 69 cases treated by thyroid extract. Sajous[43] quotes Browning as having obtained good results by use of pituitrin in cases of chorea associated with stunted growth.

In view of the rheumatic tendencies and antecedents of choreic patients, the salicylates have naturally played an important part in treatment. Here, too, different men have obtained different results.

Among the more unusual forms of treatment have been: rectal administration of salvarsan by Weil, Mouriquand, and Goyet; chloretone by Wynters; rheumatism phylacogen by Block; adrenalin by Sergent and Besset; cholesterin subcutaneously by Margarot; port wine by Ewart; and cimicifuga by Hare.

There has been considerable discussion as to the best form of administering hydrotherapy. The majority prefer hot baths for a long period of time. Collins and Gliddon[44] used wet blankets at 65° F. for one hour daily, together with daily administration of saline purges and Bulgarian milk. They reported absolute cures in 66 per cent, and improvement in 21 per cent. There seems to be no disagreement on the point that hydrotherapy in some form is of distinct benefit.

Methods of Intraspinal Treatment

Of late years therapeutic discussion has centered round the various methods of intraspinal treatment. Passini[45] claims good results from simple lumbar puncture. This Goodman[42] says has been tried and found unsuccessful. Others have thought better of it, but the results have not been striking.

About 1911 the intraspinal injection of magnesium sulphate had great popularity among Italian investigators, a procedure which has been found to be attended by considerable danger. Buchut and Devic[46] in 1912 reported death in one case following this treatment.

The form of intraspinal treatment which has aroused most discussion is that of Goodman.[47] In 1912 two of his cases of chorea developed miliary tuberculosis and died. At autopsy it was found that the tubercles were restricted mostly to the central nervous system. He felt that previous methods of treatment had failed because they had failed to reach the seat of the trouble. Arguing that chorea is due to infection, Goodman reasoned that the antibodies which must be in the blood were excluded from the cerebrospinal liquid by the choroidal plexuses. The injection of serum into the canal in his opinion makes the walls of the plexuses more permeable.

The technic consists first in suspending all drug therapy —especially salicylates and sedatives—for over five days; and in ruling out syphilis and tuberculosis. Then under strict asepsis blood is withdrawn from the arm, the serum separated off by clotting, and the serum then injected into the spinal canal. It is not considered necessary to inactivate the serum, or to withdraw a corresponding amount of spinal liquid. The patient is kept in bed for a week afterward.

Goodman reports twenty-nine out of thirty cases cured or markedly improved within three weeks. Reporting results in forty-four cases, Brown, Smith, and Phillips[48] say that in their hands the autoserum therapy has been productive of infinitely more satisfactory results than any other,—a cure of 77 per cent of the cases having been effected within three weeks. There were no recurrences in a period of over a year and a half.

Diner[48] reported three more cures, in cases who were kept in bed for a long period of time prior to treatment.

Tarr[39] reports fourteen cases, three of which were cured and two improved. He thinks the strongest argument in favor of the treatment is that acute cases can be cured before the cardiac conditions develop.

Bastedo and Tilney[40] have cited cases where the Goodman treatment has failed. Chapin and Pisek[49] say that the treatment is "questionable." Griffith[3] says his results in the few cases tried have not been satisfactory. Koplik[14] says, "It is not as yet a perfected therapy."

Langley Porter[36] recommends the intrathecal injection of normal horse serum instead of the autoserum. Citing the work of Mott, Leri, Orofici, Flexner, and Mehrtens, he says it is well recognized that the injection of foreign protein does break down the defensive power of the choroid and allow substances which ordinarily do not pass to move from the blood into the central nervous system. He points to the increased cell count after the injection of normal horse serum (sterile meningitis). He reports seven cases with marked improvement. Goodman[49] commenting on this report, says the results are "very poor."

The Discussion Summarized

The contributions of the past decade to the literature on chorea minor consist so largely of arguments and theories, and contain so many widely different forms of treatment, that our lack of knowledge of chorea is only made more manifest. We know that it is an acute disease of childhood, due in all probability to some infectious agent, corresponding clinically to the description of Sydenham; that rest, isolation, proper hygiene, and hydrotherapy are of great benefit in treating the disease; that arsenic and tonic may be of slight assistance. More than this it is safe to say we do not know.

GOITER SURVEY IN OHIO

In the three communities of Akron, Cleveland, and Warren, O., as reported by David Martin in the *Ohio State Medical Journal*, the percentage relations of school children with normal and enlarged thyroids were found to be as follows: (1) *Girls:* 9,679 (examinations extending through three years) were examined in Akron—51.36 per cent had normal thyroids and 48.64 per cent had enlarged thyroids; 406 were examined in Cleveland—62.31 per cent had normal thyroids and 37.69 per cent had enlarged thyroids; 925 were examined in Warren—75.57 per cent had normal thyroids and 24.43 per cent had enlarged thyroids. (2) *Boys:* 273 were examined in Cleveland—81.68 per cent had normal thyroids and 18.32 per cent had enlarged thyroids; 911 were examined in Warren—90.45 per cent had normal thyroids and 9.55 per cent had enlarged thyroids. *A comparison of the incidence of thyroid enlargement in relation to sex shows that in these groups of school children it is a little more than twice as frequent in girls.* The general statements that sex makes no difference in the incidence of thyroid enlargements before puberty and that during and after puberty it becomes five or six times more frequent in girls do not conflict with these figures, as the pupils examined were below the age of puberty.

EXCHANGE STUDENTS FROM BELGIUM

Twenty-two Belgian graduate students recently arrived in the United States to enter various American universities under a fellowship exchange plan instituted by the educational foundation of the Commission for the Relief of Belgium. A number of these Belgian students are graduates in medicine and will continue their medical studies in this country.

ANATOMICAL AND ANTHROPOLOGICAL ASSOCIATION OF CHINA

By E. V. COWDRY, Ph.D., Director, Department of Anatomy, Peking Union Medical College, Peking, China

CHINA is a vast country, as yet undeveloped from the standpoint of medical education, in which professional anatomists are spread over a wide area and are more or less isolated from their fellows. An urgent need for centralization and coordination of effort has long been felt. With the close of the war a period of great activity and of rapid development may be expected, during which the services that an active organization can perform will be many. In the general improvement of conditions of teaching and research and in the securing of favorable legislation regarding dissection, an association can make some headway where an individual would be greatly handicapped. Anatomists in China are also confronted with many fascinating problems, often of an anthropological nature, which necessitate cooperation in the gathering of specimens and data. Finally, it has been repeatedly demonstrated in Europe and America that the formation of an anatomical association constitutes an essential step in national organization which exercises a beneficial influence upon medical education as a whole.

Interest was therefore aroused in the formation of an association through the publication of notices and editorials in the *China Medical Journal;* and the Medical Congress, which was held in Peking during the Chinese New Year holidays from February 21 to 28, inclusive, and which attracted physicians and investigators from far and wide, offered a unique opportunity for taking definite action. The papers of anatomical and anthropological nature were gathered together and presented in the anatomical laboratory and an association was formed at the afternoon meeting on February 26, on the following basis:

Constitution

(1) The Association shall be called the Anatomical and Anthropological Association of China.

(2) The object of the Association shall be to advance the sciences of anatomy and anthropology in the far East, in the broadest sense, especially in the coordination and centralization of activities, in the improvement of conditions for teaching and research, and in the financing of special investigations and expeditions.

(3) All persons who are interested in the objects of the Association shall be eligible for membership.

(4) The names of candidates for membership shall be submitted to the Secretary-Treasurer at least one month before the meeting at which they come up for election.

(5) Each member shall pay an initiation fee of two dollars to the Secretary-Treasurer.

(6) Annual dues shall be determined at the first annual meeting.

(7) Members duly elected shall be able to assume life membership by the payment of fifty dollars, it being understood that the Association does not assume any obligations with respect to publications.

(8) Upon the recommendation of the Council persons who further the interests of the Association either financially or in other ways shall be elected patrons of the Association.

(9) The officers of the Association shall consist of a president, elected annually; and a secretary-treasurer and twelve councilors, elected to serve for a period of two years.

(10) The Council shall meet at the call of the President, in the interval between annual meetings for the consideration of expenditures, of recommendations for membership, and for the arrangement of programs for meetings. The Council shall also deal with all other matters of concern to the Association and make recommendations to it for decision.

(11) Annual meetings of the Association shall be held in close affiliation with the China Medical Missionary Association.

(12) Special meetings shall be held at the discretion of the President and at least three members of the council.

(13) For the election of members, changes in constitution, extraordinary expenditures, and dropping of members, a three-fourths vote of those present will be required; for all matters of minor import, a simple majority vote will be sufficient.

The charter membership of the Association includes Aleš Hrdlička, United States National Museum, Washington, D. C., as honorary member, and the following:

HEALTH IN INDUSTRY

Hygiene, Sanitation, Medical and Hospital Service in Relation to Industry

OTTO P. GEIER, M. D., *Editor*

TYPES OF PHYSICIANS CONTACTING WITH INDUSTRY

THE more or less nebulous notions which are generally current in regard to what are the tenets of industrial medicine as a specialty were brought out recently in the criticism of a committee report which was made to the Cincinnati Academy of Medicine on this subject, the discussion resulting in a definition of industrial medicine as a specialty and a recapitulation of the several types of industrial medical practice that have been developed which it appears worth while to give out. The scope of industrial medical practice, its importance, and its chief avenues of advancement may well be recalled in the following.

(1) *Definition of Industrial Medicine.*—Industrial medicine is the knowledge of medicine, surgery, oral hygiene, sanitation, hygiene, safety, economics, and psychology, daily promoted by and intensively applied to groups of employes, for the purpose of preventing or shortening the disability due to illness and accidents, and with the object of adjusting unhealthful working and living conditions, and of correcting unhealthful attitudes towards the conditions that surround the industrial job, thereby increasing individual efficiency and mass production.

(2) *Functions Belonging to Industrial Medicine.*—(a) Sanitation,—that is, securing for the worker clean working conditions; (b) Hygiene, including the education of the worker in personal hygiene; (c) Safety—mechanically safeguarding machinery and educating the worker to safe practices; and (d) Medical supervision, to include physical examination at time of employment and thorough periodic re-examination; diagnosis of disease and discovery of many conditions in incipiency, due to the constant accessibility of physicians; health education and treatment of individuals while employed; teaching the worker wider use of the physician for himself and family; securing to him the advice and treatment of specialists; state compensation and sickness insurance; plant mutual aids; institution of proper records for the purposes of follow-up.

(3) *Results of Industrial Medicine.*—(a) Prevention of accidents. (b) Prompt and proper surgical attention to the injured. (c) Prevention of disease and adequate treatment therefor. (d) Education of the worker to use physicians, dentists, and to refrain from patent medicine, and other harmful practices. (e) The physical efficiency of the worker increased, along with his income, thereby reducing poverty and dependency and increasing production.

(4) *Conditions of Such Practice in Industry.*—There are many types of men who think they qualify as industrial physicians.

(a) The first type is the man who merely, incidental to his private practice, takes care of a number of victims of industrial accidents. This man is surely not an industrial physician.

(b) There is a second type of doctors who are setting up emergency stations, where they take care of the accidents that occur in a great number of factories in the surrounding territory, but who do not go into the factories to study the working conditions, who know nothing of the safeguards that they should have, and do not have any interest in promoting the prevention of further occurrence of the same accidents.

(c) The third class is the physician who perhaps gives a definite portion of the day to work within the plant, and yet who makes his major income outside of the plant. This man necessarily has his heart and his chief interest in his private practice and does not qualify fully as an industrial physician.

(d) The fourth type is represented by a physician or group of physicians who undertake to serve a certain number of plants with the needed surgical attention, and who also agree to give some supervision to the matter of general plant sanitation, make physical examinations when asked for, and attend certain workers who report themselves sick when he visits the plant.

(e) In the fifth class we come to the physician who really begins to qualify as an industrial physician; he is that man who gives up his private practice to enter industry for the purpose of using his knowledge of medicine and surgery to serve the worker and the management. Here again, just as in private practice, the man is going to be a relative failure or a great success, depending upon his ability and upon the extent to which he now qualifies as a specialist in this new subject. He may be the type of man that is satisfied merely to dress injuries and simply to prescribe for men who appear in his office; or he may make a thorough study of the plant conditions, the sanitation, safety, etc., for the purpose of bringing all of his science to bear upon each individual worker, and the mass of workers, for the purpose of creating a better shop morale, raising their level of efficiency, and promoting their health, which will result in increased output. This last is the true industrial physician who really interprets the definition of industrial medicine, which states that it "is the knowledge of medicine, surgery, oral hygiene, sanitation, hygiene, safety, economics, and psychology, daily promoted and intensively applied to groups of employees, for the purpose of preventing or shortening the disability due to illness and accidents and for the purpose of adjusting unhealthful working and living conditions, of correcting unhealthy attitudes towards the conditions that surround the industrial job, as well as the community life, thereby increasing individual efficiency and mass production." EDITOR.

FUTURE OF INDUSTRIAL MEDICINE AS A LABOR POLICY

By OTTO P. GEIER, M.D., President, American Association of Industrial Physicians and Surgeons, Cincinnati, Ohio

If one would adequately discuss the subject, it would be necessary to define at least the following problems: (1) What is a labor policy and how is one developed? (2) What is the economic and social value of a labor policy in production? (3) To what extent has industry adopted such policies? (4) What is industrial medicine? (5) Does industrial medicine vitalize the development of an efficient labor policy and thus assure its future? The scope of the subject is tremendous and cannot be confined within the period allowed, so we may but undertake to discuss briefly the five queries in the outline.

Universal unrest, "verging constantly toward conflict," characterizes the complex and as yet unruled world of industry. The rapid change from the harmonious adjustment of a society consisting of small, self-centered and self-supporting units to the economic and social collisions incident to a society organized on the cosmopolitan interdependence of industrialism calls for a new ethics. A better order can come only by way of the mutual comprehension which evolves out of frequent and familiar contacts. So far, there has been applied to the complex subject of better relations little inquiry, and less logic and method.

Out of this situation arises the opportunity of the industrial physician to "bring together all the major issues of the welfare of the men" and to bring to bear on them the proper measures for their early and satisfactory solution.

When we try to measure the responsibility of industry toward world affairs we recognize that every conscientious person today is giving more serious thought to political and social questions. Never before have economic and social problems carried such national and international importance; never has the world been in such a state of flux; never before have the emotions and aspirations of the various peoples that comprise mankind been so near the boiling point; never before has universal unrest, the new *weltgeist*, shaken the foundations of so many governments. One by one have all our well rooted ideas as to the permanency of many institutions, long believed unshakable, been so forcibly cast into the discard. Nations, political systems, century old economic and political theories and practices have gradually disintegrated before this universal unrest, leaving the world face to face with the necessity of beginning anew to reconstruct our whole thinking processes so that the semblance of order may come out of the present chaos.

There exists a smug theory that every great crisis is met by the springing forth of some master minds to grapple successfully with new situations. If such supermen exist today, they have yet to make themselves known, or perchance their voices are unheard in the turmoil of the mob. If ever we needed statesmanship, it is now, and yet as we daily read the cabled news, we get the impression that nations at large are adrift.

Looming up largely in this international unrest and disorder is an industrial strife in proportions beyond imagination. Just to what extent is industry, with its rather general lack of a labor policy, responsible? Strikes, lock-outs, seizure of plants by the workers, are but signs of a general discontent with the present order of things, which has resulted in general lowering of output everywhere. And this at a time, when mass production is needed, as never before, to rehabilitate the war stricken countries, to feed and clothe millions now underfed, stricken with disease, and almost naked.

This unfortunate outlook is rapidly brought before our minds not to discourage but to stimulate, not to suggest that we be on the lookout for the superman to lead us out of our difficulties, but rather to urge the necessity of each doing his part, each playing his well studied rôle wisely, to the end that greater sanity and justice again prevail. Governmental regulation and legislation will not prove a cure. World peace and progress will evolve finally of individual right thinking and doing, rather than from old time statesmanship and diplomacy, and of no phase of the world's disorder is this more true than of industry.

It is no pleasant admission, but the leaders of industry have been slow to realize their individual responsibility not only to their own workers, but to the broad social and economic questions of the day. Too many industries have been run by single track minds, conscious only of the possible profits to be made. Such minds give no thought to human factors of management; such minds do not formulate a labor policy. Only when strikes impend do they give heed to labor relations, and then only to run to cover with other employers for purposes of defense. In brief, these types of business heads lack a constructive policy for industrial peace, and are therefore only blindly prepared for labor's method of warfare.

Labor and the Gang Spirit

If, in the past few years, labor has seemingly grasped too much for the general good, we can rightfully blame industry for failing to do its share in keeping the pendulum from swinging too widely. All men are bound to seek leadership. We all respond to the gang spirit from youth on. Organized labor in large part has supplied a certain kind of leadership, and, right or wrong in its tenets, has satisfied the human longing *to belong*, to have something to say, *to do other than merely to earn*, to be recognized as an entity, to find some form of self-expression. In times of strike and industrial strife the worried employer makes a belated effort to assume some leadership, only to find that leadership cannot be superimposed on the group or substituted for that which already exists. Industry does not attempt to build up an effective production organization over night, nor stand ready to change its managers for new ones on short notice. Even more slowly and less kindly do employees take to radical changes in their leadership.

If employers at large are dissatisfied with the character of leadership in the ranks of labor, if they would have it less radical, more constructive, they will need to help create a feeling among the average workman that this present leadership is not safe for the general good. To do so the employer will have to become as astute in his appreciation of the psychology of the employee as is the

*Read before the joint session of the American Association of Industrial Physicians and Surgeons, and the Health Section of the National Safety Council, Milwaukee, Wis., September 29, 1920.

labor leader. To accomplish this difficult task he must first inform himself about the history of the labor movement, its purposes and promises, its methods and results; for then only will he be able to discern its strengths, its weaknesses, and failures, and hold them up to light. Even then he will have no audience to sway, no group to persuade, unless he has proved by past performances that he is just and fair in his dealings with his fellow men and deserving of their confidence and leadership. Primarily, then, the employer must have a labor policy, which is exactly what too few men at the head of industry now have. Too often a blind prejudice against all organized labor is substituted or mistaken for a labor policy.

The very definition of the word policy includes a thoughtful conclusion based on all obtainable facts. In the case of a labor policy the facts must include all the basic principles of social and economic justice that enter into wage relations, necessarily tempered by the varying attitudes of the respective employer and employees. In brief, we have here the most difficult complex study confronting any human being, one that is never static or complete, but one which needs always to be adjusted and brought up to the moment if it is to remain effective. Each separate industry, more or less affected by the processes and limitations that enter into the product, has its particular labor problems which further extend to this craft of which it is a part, and all these conditions are in turn definitely molded and influenced by the composite will and desire of the labor group and the community at large.

To have a labor policy therefore, that will stand the crucial test, the management must then be willing to put real brains, energy, and heart into the study of its own attitude and personnel, of its employees and their relations to other employees and employers, as well as to the community. Management must possess its soul with patience, with forebearance, for most slowly does this knowledge unfold itself. Much wisdom will come from broad reading, more from the practical results of other similar searchers after economic truths, but the most precise information will come out of the daily organized effort at better mutual relations. Nothing will avail unless there can be established much ordinary but useful human relations between the management and the group, and by this very measure will the effort be successful. The employer must learn to talk the language of the workmen, to anticipate their misunderstandings, gracefully to accept their early suspicions in the hope that through frequent contacts, through frank and painstaking exchange of ideas, the usual barriers will finally break down.

Inject Personality into Management

In a communication recently received from a successful manufacturer, several paragraphs occur which fit into this discussion. Part of his success undoubtedly has been his ability to inject his personality into management all down the line, which finds expression through a well organized personal service department.

He states: "Employers are rapidly learning that it is just as important to have a healthy, happy, well trained, smooth running labor force as it is to have a thoroughly planned, modern building, equipped with highly organized machines made of carefully selected material, honestly and conscientiously put together, each part in thorough alignment and running without friction. We find that a shop force, once made to understand the mutuality between employer and employee, responds to our leadership and cooperates with the management in working out the daily problems of increased production and lowered costs. Industry has discovered that the establishment of a broad labor policy, in all its ramifications, is an applied science, and not a commodity that can be bought and installed in a single day; that it is an important function in management, operating continuously during every working hour of every day in the year. Only out of such constant effort will there finally result a progressive, permanent labor policy. The greatest success will come if it is begun in a small, simple way, gradually gaining the confidence of the men, each succeeding step making for a better understanding."

He then further emphasizes these points by adding, "None of these things can be substituted for a fair wage, but paying the current rate of wage, as we pay the current price for material, is not sufficient. Labor policies cannot be acquired as readily as material. Workman cannot be graded by exact mechanical or physical analysis as is the case in the purchase of materials. We may employ standards of physical fitness, make use of past records of former employment, establish extensive record systems; but the human equation still remains and the treatment of the human material must differ greatly from the handling of other material."

Finally, this successful business man vitalizes our discussion of today when he says, "The individual who represents the management in his phase of production must approach his work not only with a thorough understanding of the fundamental economic basis on which the human relations department must rest, but he must have, in a very special degree, a sympathy for the innumerable difficulties with which the average workman is confronted, and lend thereto a spirit of helpfulness. Every vestige of paternalism must be eradicated in his daily contact with the men, where he must be unostentatious, evince sympathy and understanding, fair-mindedness, and justice. When management has inaugurated such a department under such wise leadership, the greatest step has been taken for the solution of the age-long 'controversy between capital and labor.' Natural contacts are developed. Each day will bring into the open, for prompt and wise settlement, the many minor differences which too frequently have been kept in the dark, where they have festered and spread their poison, later requiring major operations to effect a radical cure."

If we take these expressions as typical of the minds of the forward-looking leaders in industry, we are face to face with the necessity of promptly providing many highly capable, conscientious individuals to take part in the development of human relations—men who are particularly qualified by character and training to initiate this newer industrial gospel. We may immediately admit that all of these better relations are predicated most successfully upon the better physical and mental health of the individual workers. So it follows that right minded physicians of executive ability, economically and socially minded, may become the very cornerstone of personal service departments.

Physicians Mold Attitudes

Industry and society need today an ever increasing group of seriously minded well trained physicians and surgeons who realize the great social and economic contribution that they may make to industry and society by special study of their opportunities to serve both the employer and the employee. In conserving the body and mind of the worker, the industrial physician is able frequently not only to add to the earning capacity of the man, but also to change the worker's attitude towards his job. Incidentally, he educates the employer to the dollar and cents value of individual and community health.

If we but stop for a moment to consider the world wide attitude of the laity towards the medical profession in general, and particularly how the physician is accepted by the industrial worker, not only as a medical adviser, but as friend and counsellor, we may at once perceive how industry, in bringing this new personality into close contact with its workers, provides a point of sympathy and understanding which can be supplied so readily by

no one of the other functionary whether he be a highly trained employment manager, a social or welfare worker, or what not. When industry accepts this non-controvertible fact that in the physician and his old time relations with the patient it has a new and definite asset, then will progress in building up personal service departments be made more quickly.

Human Contacts in Clinic

Who dare deny for a moment that the contacts produced in an industrial clinic under the supervision of a high grade medical officer are the most natural in the world; that here human helpfulness may find its best expression, free from any paternalistic slant, provided a type of service for the worker otherwise unpurchasable, unsecurable? The employee can usually secure for himself almost all of the facilities—recreational or educational—which a well developed human relations department attempts to provide, but the medical guidance is a service in a class by itself.

In establishing a 100 per cent health department service, industry supplies a type of preventive medicine which was never before conceived by the medical profession, the benefits of which even the comfortably situated and well-to-do do not enjoy. Daily supervision of health, ready accessibility of the patient to the doctor, innumerable opportunities for observation of minor symptoms and conditions, finally build up an entirely new type of preventive medicine which is bound to reflect itself in a lowered sickness rate, and therefore in a lowered death rate.

The thousands upon thousands of contacts that are made each year with the men through the medical and service departments give the employees an appreciation of the purposes and difficulties of management, and on the other hand, give the management an insight into the personal problems that confront the men. It is when this clear understanding between the two is reached that management becomes fully successful, to the ultimate gain of both employer and employee.

If the physicians connected with industry are to establish a real place for themselves and the new specialty of industrial medicine, they must intensively apply themselves to the work before them. Mere finger wrapping and the giving of gunshot prescriptions or pills inside of a dispensary connected with industry does not qualify a man to state that he is practising industrial medicine. With such professional assistance industry only fools itself in the belief that its medical department is serving the workers. This type of work is worthless to industry and has furnished the labor agitator with ammunition with which to attack the meritorious system of physical examination and medical supervision.

That physician, however, who has the support of the management and who has a broad understanding of the problems of industrial relations, modern employment methods, safety and sanitary requirements of the plant, and who appreciates the relationship between these things and the wage loss due to accident and disease is in position to make a marked contribution to industry and therefore to society.

Adequate Pay for Service

This brings us, however, to challenge industry to exercise the same care in selection and show the same willingness to pay an adequate price for properly equipped physicians that they display when hiring other executives for the plant. A cheap doctor, like a cheap manager, spells disaster. Many good physicians are finding their opportunities to serve industry in a big way made impossible by being placed under control of some narrowgauged safety or employment man whose chief concern is the size of his pay roll. Good preventive health work costs money and, unless the plant physician can sell this idea direct to the management, and from that source receive encouragement for further effort, he will soon degenerate into the routine finger-wrapper and pill-vendor previously mentioned.

We submit, then, for final and thoughtful consideration:

(1) That production is fatally low.

(2) That unrest is universal.

(3) That industrial discontent is extensive.

(4) That general unrest and industrial discontent will be cured not by legislation, but chiefly by the collective result of intense individual effort, each employer working out the problems in his own plant.

(5) That the general lack of a labor policy has contributed not a little to these conditions.

(6) That the acquirement of an effective labor policy is a man-size job, extending over years.

(7) That a constructive policy will heavily stress the value of health in the worker.

(8) That physicians giving their whole thought and energies to industry are an important factor in labor relations.

(9) That industry's power for social and economic good or evil is unmeasurable. It can and must solve its problems of labor relations. It can and should set new standards of health control.

Society Organized About Industry

If industry knew how largely it dominates life at large; if it really sensed the tremendous responsibility it bears towards society; if it could be made to see how our whole commercial, social, and economic existence is finally and absolutely dependent upon its actions; if its leaders would realize that the force and character of industrial life pulsates throughout the community, making for good or bad citizenship, for unhappy, restricted existence or for healthy, contented, constructive living; if these leaders could know to what extent good human relations in one plant leavens and makes safer the body politic, then in truth would they wield that power more largely for the common good.

The power of kings is as nothing compared to the collective power of industry when working for society's welfare. Massed within its walls are great units of society whose quality of citizenship will finally be the measure of the success of democracy. The ultimate fruit of industry is not to be looked for in its products but its real result will ever be either a discontented, unhealthy, apathetic, thriftless community, or it will be an energetic, successful, growing community, vibrant with good health and happiness, producing most per hour of employment, and adding steadily to its wealth.

Which shall be the choice? Upon the answer depends the future place in history of our industrial national life.

PHYSICAL TESTS FOR AUTO DRIVERS

Health Commissioner Copeland has made public a letter recently written to Secretary of State Francis M. Hugo, in which he suggests that amendments be made to the sanitary code making it impossible for those with defective vision or hearing, or those addicted to narcotic drugs, to become chauffeurs in New York. Death rates from automobile accidents are higher each succeeding year and automobile traffic must be controlled till it is safe.

ECONOMY OF PROPER MEDICAL SERVICE*

By GEORGE A. KINGSTON, Commissioner, Ontario Workmen's Compensation Board, Toronto, Ont.

THE task of saying something on the economy of proper medical treatment in relation to compensation is approached with a good deal of hesitation because on such a subject one is sure to tramp on someone's toes. However, at whatever risk there may be in it, I will make a few suggestions.

One has only to stop and think that the question of medical service, an item which has to be considered by someone in every one of the forty-five odd thousand cases handled in our jurisdiction in a year, and the same of course in every State and Province, to realize how intimately associated is this problem of medical aid with that of Workmen's Compensation. Even a saving of five dollars per claim, if this could be effected by the exercise of a little greater care in medical treatment, would in the aggregate amount to an enormous sum.

Accidents Fall Into Categories

Accidents divide themselves naturally into three classes: (1) those in respect to which the employer has a more or less well equipped medical and surgical organization which looks after not only first aid but subsequent attention until healing is complete; (2) those happening in an establishment where there is no medical organization whatever and where, when a man is hurt, an ambulance or carriage is called if he cannot walk or travel alone, he is sent to the doctor or hospital for attention, the Compensation Board is notified, and the employer thereafter may or may not (too often the latter) show any special interest in him until he reports again as able to work; (3) that type of case which happens in a somewhat obscure manner. The employer possibly is not informed of it, the man goes home and is treated without much regard to precautions against infection, or possibly he first realizes that something has happened when the onset of infection or other trouble is noticed, then he tries to think back and discover the cause.

The majority of accidents, of course, fall within the first two groups, but so far as the work of the Compensation Board is concerned, cases in the latter group give most trouble. It goes without saying that there is little to complain of as regards medical aid in cases falling within the first group, and it is noticeable that a well organized medical aid department in a big industrial establishment is able to very substantially reduce the number of cases requiring more than first aid.

Employees in packing houses are, in the nature of their work, peculiarly exposed to infection. One large packing house in Ontario during the first two or three years of our administration reported an unusually large number of such cases. Their attention was drawn to it. Shortly after that the medical aid provisions of our law came into force and a resident doctor was added to the staff of the establishment referred to. The difference was remarkable. Nothing, to my mind, could better illustrate the importance of getting hold of these cases promptly and it is certain that infection must have been arrested in a large number of cases by quick action on the part of the doctor and his staff. Here is where "a stitch in time" not only saves nine, but often ninety times nine.

The second group of cases has to do with the greatest number of employers. In most cases such employers probably feel that they have not a large enough establishment to warrant the expense of a resident physician, or even a first aid department. Many of them, of course, have first aid kits, but unless it is made the special duty of some one or two persons in the establishment to be in charge of such first aid boxes and the point emphasized that those so charged should by special instruction qualify themselves as real first aid men, it would probably be better in many cases that they did not attempt anything at all in the nature of a first aid dressing unless it be of the simplest nature.

The Choice of Physician

Then comes, of course, the question of choice of doctor. Much has been written on the subject: Who shall have the choice of the physician; whether workman or employer? If the doctor is what he ought to be, I am not much concerned as to whether he is chosen by the employer or the workman. In Ontario, the question of choice of doctor has given us very little trouble. There is no absolute right on either side in this matter. If any controversy arises, the Board settles it without reference to either party, and the doctor so appointed is, of course, in the nature of a referee.

In most cases the doctor is actually the choice of the employer, but here possibly is where many doctors fail to appreciate their true position. Many of them feel that having been so chosen by either employer or workman they have thus acquired what for many years before the days of the modern medical aid provision under workmen's compensation laws had come to be regarded as a sort of professional vested interest in the injured workman. They do not recognize that under the law they are given a special status. Many of them do not realize that while owing every professional obligation to the injured workman, they really are called upon to exercise quasi-judicial functions. They should be just as fair and open minded in regard to their workmen patients as the members of the boards are expected to be in administering the law. If we find a doctor constantly acting as if he were holding a brief for his patients, we can have very little confidence in his judgment. Of course we want the doctor in charge of a case to express his frank and honest opinion, but the type of doctor we complain of is the man who cannot and will not see both sides of the case. We had a case early this year of quite a prominent doctor in Ontario whom no one would ordinarily thing of calling dishonest, yet this is what happened: A man was reported as being in a serious condition from gangrene, due, it is alleged, to a frozen foot. The employer reported frostbite, but the doctor, as soon as he saw the case—as we later learned—diagnosed it at once as senile gangrene. He spoke to the employer about the case and the latter, either through ignorance or a dishonest desire to help the man, gave the doctor the story of frostbite. The doctor thereupon completed his report on the case and gave the Board frostbite as the cause of the trouble. Some slight inconsistency in the reports led us to feel that the thing was not bona fide and we investigated. As soon as the doctor learned that one of our officials was making inquiries about the case he tried to square himself by writing the Board that he was mistaken and that it was not a Compensation Board case

*Read before the Seventh Annual Meeting of the International Association of Industrial Accident Boards and Commissions, San Francisco, Calif., September 20-24, 1920.

at all; that the trouble was not due to frostbite. That claim, had it been allowed, would have cost the accident fund seven or eight thousand dollars, because the man died, and I suppose had the doctor got away with the story and the claim been allowed he would have considered it clever.

The point I wish to emphasize in giving this illustration is the duty that medical men owe to the administration of the workmen's compensation laws. They are part of the administration machinery and it is important that they be just as honest and impartial as if they had the responsibility of actually awarding compensation.

This paper is supposed to treat the subject, the economy of proper medical treatment. Perhaps much of this argument has not followed the line which the program committee expected, but it is certain that fair and honest medical reports as an aid in administration will effect very great economy, and this, in a financial sense, is just as important as the most efficient medical aid rendered to the injured man. The average doctor—yes, I believe 99 per cent of the doctors, bring the best skill of which they are capable to the aid of their patients and this, at first at all events, quite without regard to where their professional fee is coming from; and it is to the credit of the profession before the days of workmen's compensation—and probably it is the case to some extent still—that much valuable time and most efficient services were or are rendered by physicians and surgeons in every jurisdiction with the certain knowledge in many cases that no remuneration would be forthcoming. Now, however, under workmen's compensation laws things have changed. The doctor is necessarily made a part and an important part of the machinery of administration, but the laws were not made for his benefit. That is too often forgotten in his professional zeal. He is not the end, so to speak, but one of the means to the attainment of the law's clearly defined purposes, viz., the relief of the injured worker. Under most laws now full medical attention is provided for without any limitation except the judgment of the administering board. Payment of the doctor's fee is provided also. He gets paid now in every case coming under the law. Formerly, he was lucky if he were paid anything. If an insurance company was on the case and there was liability or a suggestion of it, his fee would be included in the much desired settlement, and in such cases the fee was usually liberal. Under the practice that thus grew up, doctors—many of them at least—were spoiled, but the point I have thus digressed to emphasize is, that taking the general average of doctor's fees, paid in work cases, even though the scale may be lower in some cases than the fees formerly paid, there is, I believe, much more money paid to the medical profession in the aggregate than they received under the old practice. A few doctors at first were irritated because of the control over fees exercised by the Board, but they soon came to realize that on the whole the allowances were fair and, after all, why should not a doctor's bill be subject to the judgment of a taxing officer the same as an attorney's bill in ordinary legal practice? The doctor in a compensation case has a status and an exclusive privilege under the law and is just as much an officer under the law, and should be controlled by the law, as the lawyer is and should be, who enjoys the exclusive benefit of the system of legal practice established by the law courts in this and every land.

There is need of little argument to convince members of accident boards of the importance in relation to this question of the value of full medical aid as compared with the quarter or half way measures adopted by many jurisdictions at first. I have noted with much satisfaction that many jurisdictions are amending their laws in this respect, very largely if not entirely removing the old limitations. This is as it should be. Nothing can possibly be more economical from the point of view of compensation or the saving of unnecessary compensation than to bring the most effective remedial measures to bear so as to restore the injured worker to a working condition at the earliest possible moment and get him off the fund. Surely full medical aid is much more important to this end than any half way measure.

A simple illustration will emphasize this point. I know of a certain hill in my city up which heavy loads have to be constantly hauled. It was a killing job for a team to make this grade. The city, at the instance of the humane society, provided an extra team at the foot of the hill to help each load up. Would anyone argue that the city was performing any real service if they helped the load only half way up instead of going over the top? That is really, in a sense, what the jurisdiction is doing that helps the unfortunate worker only half way up the hill to recovery, and it is surely the man who is carrying the heaviest load—that is, the man with the very severe injury and consequently needs a lift most—who is left stranded in the middle of the hill. If the voice of this Convention has any influence on the legislatures that are still backward in this important matter, I hope it will be raised with all the strength at its command.

Doctors the Key to the Situation

My political economist friend, however, sees another point and it is probably not less important. That is that every day the productive energy of a worker is checked by either total or partial disability the Nation suffers a distinct loss. He will give the exact figures in dollars which such loss amounts to. I cannot do that, but it is not difficult to multiply a million men by one day, and in terms of days we have a million days' production lost to the Nation, if there should be during the year that many men each taking a day longer in recovery than is necessary. The doctor is really the key to this situation. If he is honest, and most of them are, he will see that the man is advised to get back to work at the earliest possible moment. A few doctors, however, in fact quite a few, are often indifferent or have a sordid notion that the longer they keep the man off work and under treatment the greater will be their fee. Such doctors should be weeded out and not employed at all on compensation cases.

These matters constitute some of the problems that enter into the economics of the medical side of workmen's compensation laws. It is a very important side to the administration. It must be appreciated that the average doctor has a high sense of his professional duty. Our troubles, such as they are, are with the few whose mainspring and purpose in life is selfishness rather than service, and there should be no place for such a man within the portals of a well ordered administration.

ASSUMES RED CROSS OFFICE

Arthur G. Rotch has assumed the post of manager of the New England Division of the American Red Cross to succeed James Jackson. Mr. Rotch has been assistant manager of the Division since December, 1917, in charge of administration. He was graduated from Harvard in the class of 1903. Previous to joining the Red Cross, he was a landscape architect, with offices in Boston and New York. He is a director and member of the Executive Committee of the Infant's Hospital of Boston and vice-president of the Massachusetts Central Health Council.

ECONOMY OF PROPER MEDICAL TREATMENT*

By PAUL B. MAGNUSON, M.D., Medical Director, Illinois Industrial Commission, Chicago

IN THE October, 1919, issue of the *Annals of Surgery* there appears on the first page an article by Dr. George W. Crile, of Cleveland, entitled "The Good Surgeon," which seems to me to be so applicable not only to war and civilian surgery, but to the special surgery of industry, it is, by permission, being copied in part as a preface to this article:

The surgeons and the pathologists who for four years have intensively studied war wounds have formulated many theories of treatment—many apparently contradictory theories. Thus there have been presented the claims of the value of various chemical agents against those of no chemical agent; of moist dressings against dry; of heat against cold; of frequent dressings against infrequent dressings, and of no dressings against both; of sunlight and of electric light against occlusions; of immersion against hot air; of bacteriological control against clinical judgment; of vaccine toxin and foreign proteins against normal reaction; of wound inoculation with harmless organisms against wound sterilization; of isotonic against hypertonic solutions; paste has competed with paste, bipp with ip, sap with both, and chromic paste with all.

Does not this intensive study of infection in war wounds for this comparatively short period equal and recapitulate the more leisurely study of infection during the thirty years since Lister first proposed the carbolic spray? And is there not slowly emerging from the present conflict of opinions the same fact as that which emerged from the post-Listerian period—that the one agent of successful surgery, whether war surgery or civil surgery, is *the good surgeon?*

This paper is written in the light of two years experience as medical director of the Industrial Commission of Illinois and nine years experience as chief surgeon of several large corporations, having a great number of accidental injuries to care for every year. My criticism is intended to be constructive, and it is voiced in a spirit of helpfulness; if anybody's toes are trodden on, it is not with the intention of arousing the ire of those mutilated, but with the hope that the suggestions may result beneficially to the injured employee, to the employer, and, incidentally, to the profession.

New Attitude Toward Injured

With the enactment of workmen's compensation laws throughout the country it became necessary for industry to adopt an entirely different attitude toward injured employees. The old practice of turning the matter over to the claim department to make the lowest possible money settlement in cases where liability existed, or to the legal department when suit was instituted, had begun to give way before that all powerful weapon, public sentiment, even before the new theory that industry as a whole should stand the loss incident to injuries to employees was enacted in the law. Some of the more progressive and far sighted corporations gradually adopted the policy of administering first aid and furnishing surgical attention when men were injured in their plants. At first this was done only when the injury was caused through circumstances under which there might be liability for damages. The next step was the shop doctor, paid a certain fixed sum per annum, and then his services were made available to all injured employees regardless of liability. Then emerged a new branch of the profession known as industrial surgery, which even now is still in its infancy. This arrangement justified the expense in that it kept employees at work more steadily and frequently paved the way for a cheap settlement of a liability case. This latter consideration tended to make the doctor an adjunct of the claim department, a function which is exacted of many of them in this enlightening day and age.

The practice of relying upon the plant doctor to obtain the confidence of the injured employee and thus make smooth the way to a settlement was not, then, without justification. The employer, while none the less morally liable, was not legally liable to furnish medical and surgical treatment to injured employees, and when he did furnish it, although not from philanthropic motives, who shall say that he is not entitled to the benefit of intelligent, honest cooperation on the part of the company doctors toward minimizing the amount paid out in damages? Probably because there was no duty devolving upon the employer to furnish medical and surgical assistance, little attention was paid to the quality of such service as was furnished, and the wonder is that this branch of the profession has advanced to its present status, in view of the initial qualifications of doctors at first employed. The term "company doctor" was one of which no surgeon was proud. When the employer was in the market for a doctor it was sufficient that the applicant have a license to practise. No further inquiry was made as to his qualifications, and from my experience I conclude many employers obtain the services of their doctors now in a similar manner.

By the terms of the workmen's compensations acts in various states the duty of furnishing *necessary* medical and surgical treatment devolves upon the employer, and it does not suffice to employ a man who is not competent to give the *necessary* medical and surgical attention. Moreover, to furnish anything less than the best obtainable is economically wrong, because the cost of medical service in any serious case is an infinitesimal part of the amount the employer might be called upon to pay, and any case might develop into a serious case. It is not to be expected that the employer or an executive in a corporation is capable of passing upon the qualifications of applicants for the position of plant surgeon. In the very nature of things such an employer must either "go it blind" or rely upon the judgment of some person who knows as to the qualifications of his doctor. It is very certain, however, that if such a man were in need of a doctor for himself or a member of his family he would come pretty near making certain that the doctor he employed was qualified, and there is no real reason why he should employ a less capable physician or surgeon to look after his employees than he would to care for himself and family. Judging from industrial conditions in the state of Illinois, there are very few employers who know where their doctor was graduated, whether he had an internship in a first class hospital or an assistantship under a competent surgeon; whether he is a man of tact and force; and whether he can handle men, not only employees, but members of the claim department, who by the very nature of their occupation must be suspicious of human nature in general as a rule. I do not mean this as a stigma in any sense of the word, but a good claim man must be "from Missouri" if he is a good man

*Read before the Seventh Annual Meeting of the International Association of Industrial Accident Boards and Commissions, San Francisco, Calif., September 20-24, 1920.

for his employer, even though fair minded, and most claim men with whom I have come in contact are very fair minded and willing to do what is right if the matter is presented to them properly by the medical profession.

Rare Tact Required

The employment of a physician on this basis is a bad start, because he comes into more intimate contact with employees than probably any other head of department except an operating superintendent. He must impress employees with his ability and his fairness if he is to win their confidence. He must not let himself be involved in the settlement of any claim as a claim adjuster; he must be the friend of the men from the time they come to him until the time they leave him, and inspire confidence in both the claim department and the men. It requires a rare degree of tact to convince an employee that the company doctor is interested only in his welfare and not in the settlement of his claim at the cheapest possible figure, and it is only when this has been well established in an industry that the company surgeon becomes valuable.

I recall one surgeon who took charge of a large industry which was perfectly controlled in its organization by the union, and within a year of the time he took charge he had also been elected official examiner for that union. This same man saved that company the first year of his employment $20,000 in the claim department in spite of the fact that the number of accidents increased 10 per cent over the previous year; and as against thirty-one lawsuits filed the year before he took charge, there was one lawsuit filed the first year of his employment. In almost ten years he was on the witness stand only twice for this corporation, and in both cases testified with such fairness and impartiality to the man's condition that although in one case a $25,000 verdict was rendered against the company the attorney for the plaintiff settled the case for $6,000, because they said the medical testimony was so conclusive in their minds that they did not believe the case would stand appeal, and also said that they had been misled by medical men employed on the plaintiff's side of the case to believe that the man was hurt more seriously than it proved he was, and also because the reputation of the man acting as surgeon was too great to be combated by ordinary medical testimony. Within two years from the time this man left the employ of this corporation there were three verdicts rendered against the corporation for injuries—one of $11,000, one of $18,000, and one of $24,000—not because the injuries were any more severe than many treated before this, but because the results were so eminently bad that all that was necessary was to show them to a jury. It would be hard to convince this company at this time that a man with small training is an economical man to employ.

It is because industrial surgery has been dragged in the mud for many years, neglected and abused, and the doctor made a part of the claim department that men of large reputation will not as a rule take upon themselves the guidance of the medical work of a corporation, although the field is as much a specialty as treatment of eye and ear conditions; the general surgeon does not as a rule have the liking nor the mechanical ability to treat industrial cases. The orthopedist, on the other hand, as a rule has not had the surgical training, and surely industrial surgery involves acute surgical judgment as well as thorough knowledge of mechanics. Most men do not care about the treatment of fractures, and when it comes to the careful guidance which must be given recovery of injuries to tendons and ligaments they are not interested enough to go into details of seeing that the man receives the proper treatment.

A well equipped department of massage, electro- and hydrotherapy should be an adjunct of every large industrial surgical institution. Here we are up against the almost unsolvable problem of finding men who know how to give massage properly, who do not want to break down adhesions by force during the first treatment, who do not want to stretch muscles to the full limit at the first treatment; who know how to increase circulation, to re-establish elasticity in ligaments, gradually to break up adhesions in joints; to promote circulation and strength in muscles, to apply electrotherapy scientifically in the treatment of traumatisms to nerves, and to mobilize joints adjacent to fractured bones. We can find individuals who know one of these subjects, but the individual who knows how to apply all of them correctly is indeed a rare specimen.

I have advised massage in many cases and had the patient come back in a number of weeks without any improvement whatsoever, and upon inquiring into the kind of massage found that it consisted in the application of hot towels and the rubbing of the skin or else the other extreme of too much force, with its consequent setting up of traumatic inflammation by the too rapid breaking down of adhesions, which elicits pain and swelling and inhibits the recovery rather than stimulates it.

Haphazard Treatment Superseded

The industrial surgeon must know as well as surgery and mechanics of the human structures how and when to apply these treatments, and must see that his subordinates perform their duties properly. As massage is given now it is a haphazard sort of treatment, and certainly does not give us the results that it should under scientific management. We must have schools for the proper training of individuals for this branch of work if industrial surgery is to take its place in the ranks of specialties, where it belongs.

The question has been asked several times, "What can we gain by having a good surgeon oversee our work? Our work is so scattered that no one man can take care of all of it." This is the case in a great many instances where corporations have scattered branches. Judging from what has been accomplished, it would seem apparent that the surgeon who knows what may happen in a given industry can prepare a report blank which will cover all the essential facts and bring to him the information which he must have to judge whether a case is serious or liable to become serious and not leave it to the man who has had a comparatively limited experience. For instance, construction work involves climbing on scaffolding and ladders, from which men fall. If a man weighing 160 pounds falls 20 feet and strikes the ground on his feet, it is a fair assumption that he has not received a sprained ankle only, but probably received a fracture of the os calcis of one or both feet; and, judging from the cases that come before the Illinois Industrial Commission, most fractures of the os calcis go undiagnosed until after the damage is done and repair beyond possibility.

A fracture of the os calcis is a serious affair to a man who has to climb or walk, because in a large percentage of cases the heel is so carried upward and outward, the plantar fascia is torn, the foot is pronated, callus forms between the os calcis and astragalus, and the man not only loses the lateral motion of his foot but has constant pain when walking or standing, from the pressure of

the callus on the tendons running under the external malleolus. The plantar fascia being broken and the arch having lost its support, pronation becomes more complete as walking is tried, and the man has a foot which grows progressively worse with use and finally, in a large number of cases, loses from 50 to 90 per cent of the use of his foot, which totally incapacitates him for any occupation that involves climbing, or walking on scaffolding or uneven ground. If these cases are taken in time and properly treated, the major part of this disability can be averted, and the surgeon who prevents one of these disabilities saves a considerable portion of his yearly salary on one case alone, although it may be much better than the ordinary salary paid industrial surgeons.

Back injuries are some of the most serious with which we have to deal, and these injuries are practically never recognized by the surgeon who sees only a few scattered cases. They are called strains, and judging from past experience, most of them are told to rest for a few days and return to work, adhesive plaster strapping or hot applications being used in the meantime. The competent industrial surgeon should be an expert on the diagnosis of injuries to the spine, and instead of allowing them to run along from week to week and from month to month, they should be brought before the surgeon in charge and proper treatment instituted before the patients become neurotics, which is not at all an unusual ending.

Shoulder injuries are probably as often badly mistreated and poorly diagnosed as any other joint. We have in the shoulder an interlacing network of tendons which have an extremely poor leverage, with a number of bursæ, which are prone to develop inflammations with comparatively slight traumatisms. The usual treatment is immobilization with the arm at the side and the hand bound to the chest, which is the position of internal rotation. Adhesions quickly form around the shoulder structures, and when the arm is removed from its immobilization we not only have to overcome the adhesions but we also have to overcome the force of gravity in order to lift the arm. This is a difficult thing to do inasmuch as the normal position of the arm is at the side, and even though massage is instituted, a half hour's massage treatment is a poor attempt at mobilization when the other twenty-three and one-half hours of the day the patient's arm remains at his side in immobilization on account of the pain involved by motion. If the arm is properly put up at the time of the injury in external rotation and abduction, the muscles which raise the arm are allowed to contract, whereas the muscles which pull the arm to the side, assisting gravity, are held on the stretch. When the patient's arm, then, is relieved from the fixation dressing the muscles which have the poorest leverage are the strongest and the muscles which have the greatest leverage are the weakest but are assisted by gravity in bringing the arm back to the normal position. In this way motion is quickly re-established as well as almost painlessly re-established.

These are only a few of the points that the good surgeon knows and points that are extremely important in getting a man back to normal. They are things which the inexperienced or careless surgeon does not know and does not do.

Factors Prolonging Disability

Allowing broken limbs to remain in fixation dressings for long periods of time is another thing that prolongs disability, and the chief complaint coming before the Board after fractures is that "they just let me lay there and did nothing for me for weeks after the cast was removed." Everyone knows that a joint which has been immobilized for a number of weeks is a painful thing to move or rest weight upon. Even individuals of high mentality will not give themselves pain voluntarily, and how can we expect individuals of the average mentality of the working man to do something which others will not do? We say to a man, when we remove the cast from the fracture: "The bone is united, now you must use it." Very easily said, but not so easily done, because every time the patient tries to use it, it gives him acute pain. If the cast is kept on just long enough to allow healing and then removed each day for gentle, passive motion of the structures surrounding the joints above and below the fracture, these structures do not become hard and immovable; the circulation is kept up and the tone stimulated. There is little wonder that neurosis develop in many instances, because there is nothing done. If a man lies week after week with a painful member, the habit of pain becomes very firmly fixed in his mind, especially if he feels he is being neglected by those whom he also feels are responsible for his injury. If, however, every day he is given a half hour's treatment of the injured member, followed by gentle massage which tends to re-establish the circulation and elasticity of the parts, he not only receives results on the injured members, but he feels that there is something being done to hurry his recovery. His mental attitude remains that of a man who is friendly; he does not become morose, he does not feel abused; and when the pain becomes less severe he can be persuaded to use the member to his own advantage. It is my opinion that disabilities following fractures can be cut down in time of recovery and in percentage of disability from thirty to fifty per cent by the proper and prompt use of massage and dry heat; and that neurosis cases will largely disappear when the doctor realizes his responsibility and the employer is willing to expend money for something which seems to him unnecessary, when he is employing a surgeon to take care of his employees.

The surgeon has not the training, nor has he the time if he is the right kind of a surgeon, to give massage treatments, and he should not be asked to do it except the passive motions which are established early in the fracture cases, and these for the main part should be seen to by the surgeon so that no change in adjustment of the fractured bone occurs. It is hard for employers to realize that all doctors have not the same qualifications, but if he is the right kind of an employer he will look well into the qualifications of the surgeon who takes charge of his work as carefully as he looks into the qualifications of the superintendent of his production department and he will pay him a salary which is commensurate with the experience and training that he has had. He will not expect him to be a part of the claim department, but only a physician to his employees. No employer who is conscientious will employ a man to take care of his employees whom he would not employ to take care of his family, and it is a reflection upon the honesty of opinion of an employer who employs one surgeon to care for his employees and another to care for himself and family. It has been my experience up to this time that most employers do not go to the company doctor when they themselves are ill, which would seem to indicate that their opinion is that any doctor will do for the workmen, but they must have the best for themselves. If the employer is a good business man and looks into the subject thoroughly, I believe he will decide that the best doctor he can get, who is specially trained in industrial work, who is a graduate of a good school, who has had

an internship in a first class hospital, who has had experience under a competent surgeon, or, if possible, has taken a special course in industrial surgery, is the best investment, because such a man will inspire confidence in the employees, smooth the way for amicable adjustment of claims, make a small percentage of disability where there may have been a large percentage, prevent disabilities where they are preventable, and save his salary every three months for any large employer of labor, to say nothing of the trouble which is saved to the human race which is brought about by disabilities. Such service is adequate and, in the long run, economical.

SYSTEMS OF MEDICAL SERVICE*

By JOHN WILSON MOWELL, M.D., Chairman, Medical Aid Board of the State of Washington, Olympia, Wash

WHEN the Workmen's Compensation Act was first framed and submitted to the legislature of 1911 it had as a part of the act written into it at the time a medical aid provision for the payment of surgical and hospital bills. However, the legislature eliminated this section of the act and passed a compulsory compensation act without any provision for medical treatment to the injured.

During the period between 1911 and 1917 injured men were taken care of at the direct expense of the injured workman, either by monthly contribution in the form of contract or by paying his own bill when injured. The injured men who were taken care of by monthly contributions by contract were taken care of in a fairly satisfactory manner, but when no such provision was made it was often difficult to procure medical and hospital attention, and sometimes impossible, because of the fact that the man had no money to pay the bill himself and the compensation was inadequate to care for his hospital and surgical bills. As time went on it became more and more evident that some form of medical aid was absolutely necessary to provide efficient treatment for the injured workman.

Medical Aid Essential

The legislature of 1917 passed our present Medical Aid Act as an amendment to the Workmen's Compensation Act, but placed its administration under a separate board and made it the duty of this Board to see that the injured employees receive proper and efficient treatment for their injuries, the expense of same to be divided equally between the employer and employee. In order to carry this into effect they provided for two systems. One known as the "Contract System," whereby an employer may, with the consent of 51 per cent of his employees, enter into a contract with a physician or hospital for the care of his injured workmen. This contract to be approved by the Medical Aid Board, and the contractor to receive 90 per cent of the money contributed from such employer and his employees for medical aid as payment for this service. After having made the contract, the employees of such employer must accept the services of the contractor. In case they do not, they are required to stand the expense themselves.

It provided a second plan in what is known as the "State's Plan"; that is, all employers who saw fit not to contract, pay all of the medical aid money into the medical aid fund, out of which all surgical, hospital, and other bills for injured workmen are paid. This system gives the man a free choice of physician and hospital in the first instance, provided it is within a reasonable distance of the place of injury.

The Medical Aid Act provides that a physician and surgeon be the chairman of the Board, and the Board has dedicated to him the power of administering the orders, rules, and regulations that the Board has adopted, with the provision that anything, where the policy of the Board is involved, be considered by the Board prior to action on same. This provision of the act makes it possible for the Board, should it desire, to take up the treatment of each individual case and provide treatment consistent with its requirements, thereby achieving results that would be impossible if the Board were restricted to the necessary limitations of a legislative act that did not provide for administrative rules to be promulgated by the Board. This is one of the outstanding features of the law, because the Board may readjust its rules from time to time, if it becomes necessary for the proper administration of the intent of the act. This makes it possible for the Board to consider efficiency of treatment only. It also gave the Board authority to make a fee bill for the payment of surgical and hospital fees. By these rules the Board has restricted the free choice of physician to the first instance only.

If the Board finds that in its opinion the transfer of any bad case will hasten its recovery or lessen the permanent partial disability, the right is reserved to transfer such injured workman to such a place and under the care of some surgeon of its own choice. This allows the Board to take up reconstructive work, or postoperative work of any kind, which in its opinion is the greatest feature of the Medical Aid Act at present. We have been able to take cases that were entirely unable to work because of some condition which surgery would remedy and by having this work done the claimant was able to return to some gainful occupation and often with practically no permanent partial disability. The advantage to the workmen is apparent in a provision which is flexible enough to permit the application of such special measures as will reduce their permanent disability to a minimum. That it favors departmental efficiency goes without saying. So in the state of Washington when we come to draw a parallel between the conditions under which the workmen received medical and surgical attention prior to 1917 with the present method of handling these cases under the Medical Aid Act, we can hardly compare them.

In the first instance, a part of them received very inadequate attention. At present they all receive the best care that they can receive in the particular location in which they happen to be working, and if that locality is not up to a high standard of treatment the bad cases are transferred to where they will receive such care and attention as their cases require. This régime entails more prolonged supervision than has usually been contemplated, but the additional service is offset by increased efficiency of administration and the functional results obtained for the injured. This ideal of the best possible results for the patient serves the best interests of the Department.

*Read before the Seventh Annual Meeting of the International Association of Industrial Accident Boards and Commissions, San Francisco, Calif., September 20-24, 1920.

MEDICAL SERVICE UNDER THE MASSACHUSETTS WORKMEN'S COMPENSATION ACT*

By FRANCIS D. DONOGHUE, M.D., Medical Adviser, Massachusetts Industrial Accident Board, Boston, Mass.

FROM a most modest beginning the medical work of the Massachusetts Industrial Accident Board has gradually developed until its importance is now second to no other provision of the law, not excepting even the compensation provisions. From a little section dealing with the furnishing of medical and hospital services during the first two weeks after the injury only, the law has been amended until it now takes in every case of serious and unusual injury, provides for reasonable medical and hospital treatment and medicines for the full period of hospital care under the wise and broad interpretation given the "unusual case" provision of the law by the Board, and lately has been amended so that the Board may, whenever in its opinion such appurtenances are beneficial, order the insurer to furnish and pay for artificial appliances and thus get the employee back into industry within the shortest possible period of time.

Medical Features Most Important

In addition, the medical sections of the law have been amended to provide that the written report of the impartial physician shall be admitted in evidence as a part of the record upon which a board member may base his decision. This, in brief, is an outline of the provisions of law in Massachusetts which have exalted from an humble beginning the medical features of our law to a place among the highest and most important sections of the statute.

The following are the sections of the law governing the medical features:

Medical and hospital services (Part II, section 5).—During the first two weeks after the injury, and, if the employee is not immediately incapacitated thereby from earning full wages, then from the time of such incapacity, and in unusual cases, in the discretion of the Board, for a longer period, the association shall furnish adequate and reasonable medical and hospital services and medicines when they are needed.

Right of employee to select physician other than one provided by association.—The employee shall have the right to select a physician other than the one provided by the association, and in case he shall be treated by a physician of his own selection, or whether in case of emergency or for other justifiable cause a physician other than the one provided by the association is called in to treat the injured employee, the reasonable cost of his services shall be paid by the association, subject to the approval of the Industrial Accident Board. Such approval shall be granted only if the Board finds that the employee was so treated by such physician, or that there was such emergency or justifiable cause and in all cases that the services were adequate and reasonable and the charges reasonable.

Board may order insurer to provide and pay for artificial appurtenances.—In any case where the Board is of opinion that the fitting of the employee with an artificial eye or limb or other mechanical appliance will promote his restoration to industry it may order that he be provided with such artificial eye, limb, or appliance at the expense of the insurer.

Examination of employee by physician for Board (Part III, section 8).—The Industrial Accident Board or any member thereof may appoint a duly qualified impartial physician to examine the injured employee and to report. The fee for this service shall be five dollars and traveling expenses, but the board may allow additional reasonable amounts in extraordinary cases, and the association shall reimburse the Board for the amount so paid. The report of the physician shall be admissible as evidence in any proceeding before the industrial accident board or a committee of arbitration, provided that the employee and insurer have seasonably been furnished with copies thereof.

Fees subject to approval of Board (Part III, section 13).—Fees of attorneys and physicians and charges of hospitals for services under this act shall be subject to the approval of the Industrial Accident Board. If the association and any physician or hospital, or the employee and any attorney, fail to reach an agreement as to the amount to be paid for such services, either party may notify the Board, which may thereupon assign the case for hearing by a member of the Board in accordance with the provisions of this Act. The member shall report the facts to the industrial accident board for decision, and the decision shall be enforcible as provided by Part III of section eleven.

Hospital records as evidence (Part III, section 19).—Copies of hospital records kept in accordance with the provisions of chapter three hundred and thirty of the acts of nineteen hundred and five, as amended by chapter two hundred and sixty-nine of the acts of nineteen hundred and eight, and of chapter four hundred and forty-two of the acts of nineteen hundred and twelve, certified by the persons in custody thereof to be true and complete, shall be admissible in evidence in proceedings before the Industrial Accident Board, or any member thereof. The Board, or any member, in its or his discretion, before admitting any such copy in evidence, may require the party offering the same to produce the original record.

The duties of the medical adviser embrace the systematization of all the vast amount of medical information required under the Workmen's Compensation Act; advice with reference to all medical problems; supervision over the work of impartial examining physicians; the direction of expert help and testimony in certain exceptional cases; the outlining of the essential medical facts required to decide whether disputed nonfatal and fatal cases are covered by law; and the preparation of such cases impartially for hearing in order that the provisions of the act may be made effective speedily and with the least possible cost and annoyance to the parties at interest.

Appointment of Impartial Physicians

The work of advising the Board on the appointment of impartial physicians is a duty of the medical adviser, for the purpose of having a uniform system based on expert knowledge of the requirements of the different cases that arise, and to permit of the selection and training of physicians in a manner that will insure impartial examinations and reports according to the technical requirements of the compensation law. As far as possible, also, examiners are assigned to cases according to geographical proximity to the residences of injured employees. In some instances cases are of such nature that it becomes necessary for them to report for examination in Boston or in some other large center where the facilities for examination are better than in the immediate locality where the employee resides. When this action is necessary or advisable the expenses of the employee incident to the trip are paid by the insurance company. In all cases the aim in selecting physicians is to provide a man whose training and experience fit him to examine and report expertly according to the special features

*Read before the Seventh Annual Meeting of the International Association of Industrial Accident Boards and Commissions, San Francisco, Calif., September 20-24, 1920.

involved in the case, not only as to past disability but as to future treatment.

In connection with the assignment of impartial physicians according to the nature of the case and location, some interest may be attached to a brief statement of the process by which the impartial reports are handled at the office. Upon receipt of impartial reports these are in all cases first read by the medical adviser to make certain that the report properly covers the necessary points involved in the case. Copies are then made and sent to the employees, insurance companies, and, in some instances, to other persons who have a direct interest in the case. The impartial examination is not related in any way to the examinations which the insurance company is permitted by law to have performed in its own behalf, by a physician appointed outside the jurisdiction of the Board. The impartial examination is to assist the Board and the interested parties in obtaining reliable medical opinions which under the law have the weight of being entirely separated from any direct interest either in behalf of the employee or the insurance company.

Every insured fatal case that comes to the attention of the Board through an accident report, or otherwise, is referred to the medical department in order that all necessary steps may be taken to procure proper and adequate records, such as hospital reports, statements of physicians, and copies of autopsy reports when these have been made. Informal opinions are stated in these cases to indicate the probable connection between injury and death.

Opinions are given, also, on the records in cases in which there is a possible question of additional compensation on account of amputations, reduction in vision to one-tenth of normal, or other specified injuries such as may render permanently incapable of use members of the body, including arms, legs, fingers, toes, or phalanges.

Another important function of this department here briefly described is the action taken upon disputed medical bills. In case of dispute, although the physician has the right to have a formal hearing, the practice in general is to endeavor to adjust the matter if possible on the basis of an informal opinion by the Board based on the records in the case. In such cases the attending physician or the hospital is requested to submit a copy of the bill in dispute, and to answer a form set of questions describing the nature of the case and the treatment given. With this information and the other records in the case, an informal opinion is given as to the reasonableness of the bill on an industrial basis. Many cases are settled in this fair and impartial manner, although neither side is thereby prejudiced from having a formal hearing and decision based on the evidence submitted.

What Constitutes an Unusual Case

Another important, and at times perplexing, question with relation to medical attention is "What constitutes an unusual case requiring the payment of medical and hospital bills beyond the statutory period of two weeks?" The reasoning of the Industrial Accident Board for the consideration and determination of this question in each individual case according to the evidence is epitomized in the following extract from the case of John Brady, Brockton Hospital, Dr. Barrett *v.* United States Casualty Company:

The only case in which the question as to the right of a physician to the payment of his bill for a longer period than two weeks was before the Supreme Judicial Court of this Commonwealth is Huxen's case (226 Mass. 292). In this case the court said: "It is not in an ordinary case requiring longer medical attendance that the discretion of the Board may be exercised to charge this attendance to the expense of the insurer. It is only in unusual cases that they may do so. There would be grave doubt whether a case where the employee is able to go from his home in Cambridge to an office in Boston could be so unusual as to be within the purview of the act."

The word "unusual" is defined as follows:

"Of a character, number, or size not usually met with; uncommon; infrequent; rare." (Standard Dictionary of the English Language, Funk & Wagnalls.)

"Not usual; uncommon; rare." (Webster's Dictionary.)

"Not usual; not frequent; not common; rare; strange." (Century Dictionary.)

The evidence shows that this case is unusual; that it is a case out of the common run of cases, in view of the nature of the injury and the complications following such injury. The usual case and the usual personal injury arising out of the employment are those cases and injuries which require ordinary medical treatment and care, and go along uneventfully to their termination, and they may or may not require treatment for a longer period than two weeks. These cases are not within the discretion of the Board to allow further medical and hospital fees after the first two weeks. A case may be unusual because the nature of the injury, its particular location, and its extensiveness necessarily entail a prolonged disability; that is, longer than the usual. It may be unusual because of any interruption of convalescence of such a nature as not to occur commonly in that particular class of cases, and because it is likely, unless specially treated, to jeopardize the probability of a speedy recovery from a medical standpoint and the employee's early restoration to his position as a wage earner. The employee's status with reference to his support of others is a factor which may be taken into consideration in determining whether a case is unusual. Under the usual classification will come so-called minor injuries, minor amputations, uncomplicated by sepsis, and all injuries or complications following them, the services of specialists, special nursing, and hospital care. Under the unusual case classification may come major injuries, compound fractures, injuries followed by sepsis, some major amputations and operations, serious pelvic and back injuries, and injuries requiring special apparatus or the services of specialists.

This was a very serious injury; the employee was in a critical condition; the stitches pulled out; and a secondary operation was necessary. The report of the injury shows that the employee had a dependent mother. It was a case that required hospital care and attention if the man was to recover at all, and particularly if he was to be restored once more to any degree of efficiency.

Probably the greatest factor in the satisfactory carrying out of the Massachusetts law has been its intelligent development along medical lines.

Eliminate Professional Witness

The old form of controversy, by presenting witnesses depended upon the weight of the evidence presented at for and against the claimant, so that the man's rights a hearing, has been materially modified by the naming of so-called impartial physicians. It was found that the malingerer or fakir in Massachusetts was almost an unknown quanitity, and that when a man came to the Board with a claim, 99 times out of 100 it was a just claim. The question, then, came on selecting doctors to examine these claimants, with the idea that a specialist in restoration of function was needed rather than a doctor who would say, "Yes, the man is disabled," or "No, the man is not disabled." In the early days of the act, the insurance companies did not avail themselves of the impartial examiner, because examiners were not picked out along special lines. With the advent of the medical adviser, taking office in December, 1914, there was a great increase in the amount of work the insurance company put up to the medical adviser for aid in solving.

It is, of course, manifestly impossible for the medical adviser to examine all disputed cases, or even a small

portion of them; and if it were physically possible, it would be an extremely unwise, not to say dangerous, thing to have any man placed in the position of examining accident cases in conference, again to express his opinion at a formal hearing, and then to insist to the full Board that his opinion was the end of the medical law and must be accepted. The great success of the Accident Board has come from the utilization of the best medical brains in the commonwealth. Members of the medical profession consider it an honor to serve as impartial examiners and are willing to make some sacrifice fully to preserve this feature of the law.

One of the difficulties that the Industrial Accident Board faces constantly is to fairly pass upon the injuries of a man who chooses his own doctor and who does not choose wisely, or the rights of a man who is taken to a place which holds itself out to be a hospital. The time will come when the State Board of Registration in Medicine, or some other state board, will supervise these hospitals, will check up their results, and will indicate whether or not they should be allowed to continue, and to what extent they will be allowed to go in treating complicated cases.

From an administrative standpoint, the Industrial Accident Board is obliged to consider all doctors registered under the laws of Massachusetts to practice as being qualified. But there is much incompetency in the treatment of fracture cases, and the results in many cases do not justify the payment of the sums of money charged for the treatment. In this particular regard, we approach old fashioned common law tort case, in which the worse the result, the greater the financial return to the doctor—and sometimes to the lawyer and injured party.

Recently I was in a doctor's office and looked over a group of certificates, imposing and impressive in their display, one of which certified that he had taken a course in anesthesia at a well known New York polyclinic; and a second certificate was so unique that I copied the wording for future reference. Let me read it to you.

School of Pathology and Operative Surgery.—This certifies that Dr. ——— has completed in a most thorough, practical, and scientific manner the prescribed course of surgical operations, including operative surgery on the cadaver, and is thoroughly competent to operate on the living. SIGNED AND SEALED.

What are we going to do about it?

I have outlined rather briefly, but as fully as need be, the medical provisions of the Massachusetts act. They may not appear to be as complete as some of the commonwealths numbered among the members of this organization. But this I may say, in all truth, and in justice to the Commission which has charge of the administration and interpretation of our law:

Outside of a law providing specifically for complete medical and hospital care for the full period of incapacity, the Massachusetts law, as interpreted by the members of the Industrial Accident Board could not be improved upon. The administration of medical service under the law as it now stands is sufficiently flexible to provide adequate care in most cases. Personal attention to the necessities of each case is given by board member and medical adviser, with the result that in practically no case where expert treatment is required or indicated does the employee go without it, and under our present plan of making one complete job of the medical care and cure of each incapacitated employee and getting him back into industry with the least possible loss of time at a suitable job, we believe that we are solving in a practical and economical way the problem of the man whom industry has maimed and handicapped.

AMERICA'S CHILDREN

Most of us take it for granted that American children go to school, receive a fair education, and, taking it by and large, are much more fortunate than the children of any other nation that we need not worry about them. But how true is our assumption? At least one-fifth of all American children between ten and fifteen are out of school earning their own living.

In one industrial center in Massachusetts, a state that stands high on our educational roll, only one child in ten finishes high school, while sixty-six out of every hundred leave school for work the moment the compulsory school law releases them. This is true in a greater degree in other states, some of which still have no adequate schooling law, require only a knowledge of English of children leaving school for work, and have a school term of only eighty days. The result is that almost one-quarter of our population is illiterate.

In fourteen states this year it is reported that child labor has increased, more children having left school for work than in 1919. Many of them are employed in industries not regulated by the federal tax on child labor; they may be employed nine, ten or eleven hours a day; they may be worked on night shifts; they may even work at trades known to be dangerous—and the child in industry is just three times as likely to suffer accident as the adult. Massachusetts, again, is more careful of her children than many states, yet in Massachusetts last year there were 1,691 industrial accidents to children under sixteen, ten of which were fatal and sixty-two of which resulted in permanent partial disability to the child.

Is all this a square deal for American children?

It is to consider such facts, to bring the child welfare situation home to all of us, that the National Child Labor Committee appoints the fourth Sunday in January each year as Child Labor Day. In 1921 it falls on January 23. It is observed not only in Sunday schools and churches, but on January 22 in synagogues and on January 24 in schools, colleges, clubs, and other organizations. Pamphlets and posters are distributed by the National Child Labor Committee for use by those interested in observing the day, and anyone who wishes such material should write directly to the National Child Labor Committee, 105 East Twenty-second Street, New York City.

It happens that Child Labor Day comes this year at the end of National Thrift Week, and so the Committee points out that the conservation of children may well be considered as an item in the larger national thrift. "Every child without an education today," says Owen R. Lovejoy, secretary of the National Child Labor Committee, "means an illiterate citizen tomorrow; every child who is overworked today means a dulled, unhealthy citizen tomorrow; and every child who enters a low-wage, blind alley occupation today, without means of advancing himself, means a poverty stricken, inefficient citizen tomorrow, very possibly a charge upon the nation. What kind of citizens do we want, and what kind are we making?" All physicians who have the human view must interest themselves in child labor.

Environment in nature, with all that it connotes, is one of the regulating factors which helps to insure the survival of the fittest. But in human life so much of our environment is artificial that it kills many who by heredity, were well fitted to survive, and protects and shields others who, in virtue of their physical handicap at birth, would have little chance of surviving were they not specially nurtured and surrounded with all the comforts that wealth and devotion can procure.—*Mackenna.*

SCIENCE AND POLITICS IN RELATION TO THE PROBLEM OF MILK SUPPLY

A RECENT statistical survey of the problems of our national food supply by Professor Raymond Pearl[1] brings out with clearness the enormous importance of dairy products in the American dietary. Wheat, pork and dairy products, as indicated in the table below, give us about three-fifths of our food energy and our body building materials; and of these three, dairy products are of supreme importance because they furnish the complete proteins, the vitamines and the calcium which are lacking in such cheaper energy sources as the cereals.

Percentage of the Total Food Supply of the American People Furnished by the Three Principal Elements in Our National Dietary

	Calories	Proteins	Carbohydrates	Fats
Wheat	26	29	42	2
Pork	16	11	..	40
Dairy products	15	20	5	27
Total	57	60	47	69

In view of these facts it would seem obvious that any discoveries tending to facilitate the production of a better and cheaper milk supply should be enthusiastically welcomed. The advance made during the past few years in the preparation of various dried milk powders seems to promise important progress along this line. Whole milk powders are now on sale which may be beaten up in water so as to make a reasonably satisfactory product in the individual household; while reconstructed milk made from dried skim milk powder and butter can be made up on a large scale so as to be scarcely distinguishable from the best fresh milk.

The same selfish local interests which have so long hampered the development of the use of butter substitutes are beginning to manifest themselves in a campaign against milk powders. In one state, for example, the Department of Agriculture and the State Board of Health have issued the following regulation:

The sale of condensed, evaporated or powdered skimmed milk is allowed, but it shall be unlawful to sell the said condensed, evaporated, or powdered skimmed milk except under the following regulations: in addition to compliance with all existing laws, the said condensed, evaporated, or powdered skimmed milk to be sold in packages or containers containing not less than one gallon or ten pounds of said condensed, evaporated, or powdered skimmed milk, which packages or containers shall be hermetically sealed at the time of sale; also that at the stores, shops or places where such condensed, evaporated, or powdered skimmed milk is sold a sign must be displayed upon which is printed in black letters at least five inches in height and worded as follows: "Condensed, evaporated, or powdered milk should not be fed to babies or invalids; it has not the food value of whole milk."

Such legislation is absolutely unjustified. It seems probable that the antiscorbutic vitamine may be weakened by drying as it is weakened by pasteurization and by the aging of raw milk. If such should prove to be the case, the remedy lies in the use of antiscorbutics, which are always desirable when cow's milk is the entire food of the infant. There is no reason to believe that the really important vitamine in milk, the Fat Soluble A or growth producing vitamine will be in any way affected by modern dehydration processes. The use of dried milk powders would go far to eliminate the sanitary dangers which surround the use of raw milk supplies; and it should materially reduce the cost of the product by cutting out 80 per cent of the freight charges for transporting the natural product and by eliminating the losses due to spoilage in transportation. The development of the use of milk powders is a logical and scientific tendency which carries much promise for the conservation of our food supplies. As such, it should receive the sympathetic consideration of all public health authorities. Editor.

THE AGE INCIDENCE OF TUBERCULOSIS

WHEN Dr. John Brownlee[1] first published his remarkable researches on the age incidence of tuberculosis, most students of the subject were frankly puzzled by the results attained. The curves presented were strikingly significant; they certainly showed that in certain districts in England the highest mortality from pulmonary tuberculosis is reached between the ages of 20 and 25, in other districts between 45 and 50; while in still others the maximum peak comes as late as sixty years. On the other hand, Dr. Brownlee's conclusions that there were three different types of tubercle bacilli involved, respectively, in the "young adult," "middle age," and "old age" types of the disease involved such far reaching biological assumptions, without any direct experimental proof, that bacteriologists could hardly be expected to adopt them with alacrity.

A stimulating and suggestive article by Dr. S. Lyle Cummins[2] furnishes us a more plausible explanation of the observed facts and forms a most important contribution to the general etiological theory of tubercu-

1. Brownlee, J.: National Health Insurance, Medical Research Committee, Special Report, Series No. 18, 1918, and Series No. 46, 1920, London, H. M. Stationery Office.

losis. The author is interested primarily in the difference between the low resistance to tuberculosis exhibited by primitive peoples who have been previously protected from extensive contact with the disease, and the relatively high resistance observed in communities where tuberculosis has long been prevalent. The latter condition he naturally attributes to acquired immunity; and the most striking part of the discussion is his analysis of the Brownlee curves, in which he shows that the "young adult type" occurs in remote regions like the Shetland Islands, the Scotch Highlands, Ireland and Norfolk, where infection—and hence acquired immunity—would naturally be least. The "middle age type" occurs in London, Lancashire, and Northumberland, and is the type to be expected in urban and industrial regions where infection has long been widespread and acquired immunity high. Finally, the "old age type" is particularly associated with definite industrial conditions, involving exposure to mineral and metallic dusts—tin mining in Cornwall, for example—and is the expression of a naturally good resistance which is ultimately, but slowly, broken down by a particularly detrimental environment. The delayed age incidence of tuberculosis in the very dusty trades is a familiar fact brought out by Hoffman and other students of industrial insurance statistics in this country. Dr. Cummins' thesis deserves the careful study of all who are interested in the etiology of tuberculosis, and it seems likely that he has discovered the correct explanation of a complex and obscure phenomenon. QUANTITATIVE FACTORS IN THE CONTROL OF VENEREAL DISEASE

THE progress which was made in the control of venereal disease by the Army and the Navy of the United States during the World War was a cause for the profoundest gratification; and it is probable that the Nation gained, in increased vitality as a result of the campaign against venereal disease, far more than it lost in all the battles in which our troops took part.

The analysis of the factors which contributed to the results attained is therefore an interesting and important task. A year ago, Colonel Ashburn[1] presented a valuable study along this line which was based on a questionnaire to which replies were received from 13,648 men serving in the American Expeditionary Forces. From these data the conclusion was drawn "that anti-venereal measures are effective in the following order: (1) Those that keep men chaste. (2) Those that diminish the opportunities for sexual contact, especially efforts at the suppression of prostitution. (3) Those that diminish the dangers of contact, especially venereal prophylaxis. (4) Those that exact punishment."

Colonel Ashburn believes from the replies to his questionnaire that approximately one-third of the men abstained entirely from sexual intercourse while in France and that another third indulged so infrequently as to make the chance of venereal infection small. Next to chastity, prophylactic treatment was, of course, most effective in reducing venereal disease, the proportion of irregular contacts to cases of venereal disease being about 30 to 1 without, and 90 to 1 with, prophylactic treatment.

Recently Dr. J. E. Moore[2] has presented detailed and convincing evidence in regard to this last factor of venereal prophylaxis, based on a very careful analysis of the experience obtained in the district of Paris, where the problem was of course a peculiarly difficult one. In this district the suppression of prostitution was almost impossible and the large number of "casuals" in the city on leave or passing through, so hampered the carrying out of the first two of Colonel Ashburn's measures that prophylaxis proved the largest single factor in the control of venereal disease. The excellent records of prophylactic treatment which were kept made it possible to check up the claims made by infected men as to previous prophylactic treatment and showed that instead of 40 per cent of all cases in the Paris District developing after prophylaxis, only 15.2 per cent of the cases so developed, and in 9.6 per cent of these cases prophylaxis failed because of the patient's own fault (delay in taking treatment, etc.). Only 5.6 per cent of the cases developed after efficient prophylactic treatment and Dr. Moore estimates that this represents an efficiency of 99.6 per cent for venereal prophylaxis, based on the group of exposed men who received the treatment under fair test conditions. DR. RENE SAND

Press Illustrating Service.

The many friends in America of Dr. René Sand, professor of industrial medicine in the University of Brussels, Belgium, will welcome the publication of his work on "Organisation Industrielle Médecine Sociale et Education Civique," which is the result of studies made on trips to England and to the United States on official missions during the war. This material he has brought together under three main subdivisions, the first tracing the development of industrial medical service, the second dealing with state and civic medical problems, and the third outlining educational facilities. The book is a much more comprehensive survey of the subject than we have made of our own institutions and will be fully reviewed for the benefit of the readers of MODERN MEDICINE.

THE EXTENSION OF MEDICAL SERVICES

By J. MIDDLETON MARTIN, B.A., M.D., County Medical Officer of Health and School Medical Officer, Gloucester, England

IT has long been recognized that "the organization of medicine has become insufficient and that it fails to bring the advantages of medical knowledge adequately within reach of people." The words quoted are taken from the Interim Report of the Medical Consultative Council for England to the recently formed Ministry of Health, and the circumstances leading to this opinion probably exist in all countries.

In England the position has become more complicated owing to responsibility for the treatment of various affections and of various groups of the community having been taken over by the Government and distributed amongst different Government departments and different local authorities: of these conditions a long list might be made and may here be instanced by the system of medical care of insured persons, the schemes for the treatment of tuberculosis and venereal diseases, and for the medical supervision of children attending public elementary schools.

Effective for the Community

The Consultative Council in their report deal with the matter in the broadest possible manner and outline a service which would undoubtedly result in the great resources of medicine and surgery being used much more effectively for the benefit of the community than is practicable under present conditions of individualistic work.

Quite shortly, the effect of their proposals would be to secure coordination and development of all existing agencies whereby medical practitioners at the periphery will be kept in close relationship with the resources not only of the large general hospitals and their staffs, but also of the specialist hospitals and services; whereby, as a corollary, each patient will be readily brought to the source where he can receive the particular treatment his condition requires. Throughout their report the Council have in view the necessity of early and preventive treatment which is essential if the science of medicine is to justify its existence and if the community is to reap full advantage of medical progress.

These objects they aim at achieving by a coordinated service admirably illustrated in the diagram: in this diagram are shown as the center the very fully equipped large General Hospital—with all its specialist services—in touch with the teaching hospital, which is often a university, on the one hand, and closely linked on the other to various smaller centers which are equipped according to their varying needs in the towns and villages in the neighborhood. At the latter, described as Primary Health Centers, the medical services will be given by local practitioners, and specialists from the Secondary Health Center—the large General Hospital—will there attend patients in consultation on cases with the practitioner.

The Council state that "the scheme may be usefully illustrated by taking the actual example of Gloucestershire, where the local authorities in the county and its towns, the hospital authorities and all the doctors have agreed on a plan of services not dissimilar in its aims to the one set forth in this report." The scheme referred to is known as "The Gloucestershire Scheme for the Extension of Medical Services" which has been approved by the Ministry of Health and is now being brought into operation. The principle of the scheme was first put forward in April, 1918, in response to a request from the Ministry of Pensions for suggestions for the more adequate treatment of soldiers and sailors, and has developed to enable the County Council to carry out its obligation to provide treatment in connection with (1) venereal diseases, (2) tuberculosis, (3) school children, and (4) maternity and child welfare.

The diagram shown explains the proposals concisely, and in the scheme it is shown how readily its scope can be enlarged to include any branch of medical work.

The fundamental centers of the scheme are the General Hospitals at Bristol, Cheltenham, Gloucester, and Stroud; and the county is divided into four corresponding hospital areas: in suitable positions in these hospital areas, centers for out-patient treatment—described as Hospital Out-Stations—of a comparatively simple character in the first instance, with waiting room, consulting room and dressing rooms, are being arranged so that when all fifty-two are opened there will be one within, on the average, three miles of every part of the county. These will be equipped as simply as possible, and the resources gradually improved as circumstances show the desirability: beds will be added in suitable cases. Wherever possible, the Out-Station will be attached to a Cottage Hospital, of which there are eleven in the county, or will be made the residence of the district nurse.

Local Practitioners Serve

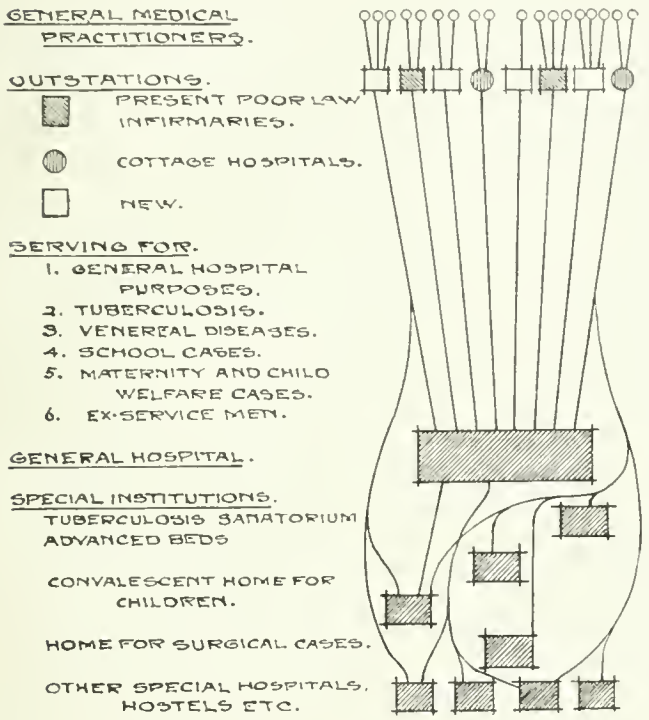
The personnel will consist of the local practitioners, who will each take duty for six months in turn, and, instead of working independently—as under present conditions—they will have at their backs all the resources of the General Hospitals, including the staffs, members of which will attend at the Out-Stations for consultation on cases with the medical officer at each. Ambulance service is proposed for the General Hospitals and suitable cases will be sent readily to specialist institutions. District nurses will act under the instructions of medical officers. The alternative is the development of the system of appointing whole time officials for each service—venereal diseases, tuberculosis, school children, etc.—as each new branch of work is undertaken by the community; but it is strongly felt that the extension of this practice would tend to depreciate gradually the standard of medical services in the country.

Very important features of the Gloucestershire Scheme are the arrangements for its management. It is controlled by a Board of Management under the County Council, consisting of representatives of the Council and of the hospitals, which has a strong Medical Advisory Committee, formed of representatives of the hospital staffs and out-station medical officers in equal numbers.

Earlier in these notes mention was made of the numbers of authorities and bodies concerned and one of the chief initial difficulties was securing the concurrence of government departments, local authorities, hospitals, and medical practitioners. That the cooperation of all was secured shows that the scheme is recognized as being on sound lines; but, in so far reaching and, to a certain extent, such revolutionary proposals there remain the difficulties of practical working of a pioneer scheme to be overcome.

These are being approached in so enthusiastic a spirit by all concerned that there can be no doubt but that they will be surmounted as successfully as the initial difficulties. Indeed, one very great advantage of the scheme is the close association of all medical men—consultants and general practitioners—with one another, from which incidentally there must be important consequences in the direction of improved medical service generally.

GLOUCESTERSHIRE SCHEME FOR EXTENSION OF MEDICAL SERVICES.



J. M. M.

COUNTY MEDICAL OFFICER OF HEALTH.

The problem of medical care for the scattered populations of county areas is very different from urban conditions, under which it is possible to extend medical service by so simple a means as the opening of a treatment center and appointing a suitable officer. County conditions make it necessary that all, or at least the greatest number, of the persons resident in the area can attend the centers. Obviously, the primary centers must be equipped to handle all classes of cases, the examination and treatment of the special groups being provided for by the attendance of specialists, who are regularly available in the way of consultation. Existing machinery is, of course, taken advantage of in the development of schemes.

Briefly, the Gloucestershire scheme consists in the opening of out-patient departments at eleven Cottage Hospitals and forty-one new out-stations of the general hospitals, somewhat on the lines of existing tuberculosis dispensaries with consulting room, waiting room, and dressing rooms, so that one will be accessible within a radius of about every three miles of the county, at which stations the out-patient treatment of all the special classes of persons for whom provision is made at the public expense will be available for all the people.

The utility of the out-stations will be increased by making them available, by arrangement with the County Council, for such other medical services as out-patient treatment and consultant service under the National Insurance Acts. In addition to medical services, intermediate treatment will be given by nurses in school cases, etc.; by trained orderlies for venereal diseases; and by masseurs and masseuses for ex-service men as needed. The machinery thus created lends itself to expansion for the provision of other medical services, e. g., extended treatment of insured persons; general treatment of persons such as can be given at out-patient departments of hospitals, and schemes for the care of the sick and infirm. For the fullest advantage to be derived from the scheme, ample opportunity should be afforded for the pathological and bacteriological examination of specimens, for which purpose close association with a well equipped and efficiently staffed laboratory is essential. The scheme would be incomplete if it did not from the outset embrace provision for linking up all existing specialists' services, institutions, and special hospitals. Very important branches to be developed must be research and prevention, and in this connection may be mentioned abnormal mental development for which less has been attempted than for many other conditions and diseases. Such a scheme of the Medical Consultative Council as outlined health organization in connection with which all medical officers and nurses engaged therein should have definite health functions.

The chief arguments that have been urged against the scheme of the Medical Consultative Council as outlined in their Interim Report are that it is impracticable and that the cost will be prohibitive. That neither objection is sound is shown by the fact that effect is being given in Gloucestershire to the scheme above outlined similar in its essentials to that foreshadowed in the Interim Report.

AREAS AND DATA PERTAINING TO HOSPITAL DISTRICTS

Hospital District	Area in Acres	Houses	Population	No. of Centres (Hospitals and Out-stations)*		Approximate average per Centre (Hospitals and Out-stations)

*Excluding General Hospitals.

The fundamental centers of the scheme are the General Hospitals at Cheltenham, Gloucester, Stroud, and Bristol. Suitable positions for the Primary Health Centers being determined by the needs of each particular district.

THE PUBLIC HEALTH MOVEMENT IN THE LIGHT OF MODERN PSYCHOLOGY*

By DONALD B. ARMSTRONG, M.D., and EUNICE B. ARMSTRONG, M.A., Framingham, Mass.

BACK in 1908 or thereabouts the New York Health Department first published the slogan "Public Health Is Purchasable." Still earlier the slogan "Tuberculosis Is Preventable and Curable" had been spread across the country. Both these campaigns of education were founded on the idea that if the public knows the facts it will take proper action,—a trust in information and in the success of a reasonable appeal to the intelligence of the public which continues to inspire as many campaigns of education as ever, and to which the partial or complete failure of those same campaigns is due.

The newer psychology more and more points to a definite basis of reaction and promises possibilities in the way of definite prediction in matters relating to human conduct.

The heterogeneous materials of the unconscious mind, through processes of unconscious mentation, are continuously being organized, forming the bases of the physiologic "sets" which control impulsive action.

Full fledged opinions, ready made and serviceable, may evolve; or skulking desires but imperfectly suppressed, may evade the censor and motivate unsocial reactions.

The control of individual or mass response depends upon making the appeal on the save level at which the resistance has arisen.

Large public health budgets have not become too easy to obtain. We persist in a willingness to spend more for a battleship which will be scrapped before it is used than for the assurance of protection against typhoid fever. Knowledge of the measures of personal hygiene which will largely prevent infection has not even halved the death rate of the preventable infectious diseases. Our most successful health campaigns have often been carried out autocratically, by military governors, with no appeal to the intelligence of the population concerned.

Cannot Compel a Health Democracy

Yet we cannot compel health in a democracy and, if intelligence alone in a democratic population does not suffice, how is our increasing knowledge of measures for health to be put to work?

The constant need for trained men for public health administration is gradually being supplied, but that alone will not greatly improve public health. Even with the knowledge and the men now available, our health conditions are at least 50 per cent below what they should be if our existing resources in men and information were fully utilized. It is not enough to increase the supply of health goods. They are useless unless the public purchases and uses them. How can this be accomplished? Has it been accomplished in the past, and if so, how?

Certain campaigns of health education have produced the results expected. They have been no more reasonable than others which have failed. Yet they have won the cooperation of the public; and so, and not otherwise, can a democratic health or social program be effected. The Red Cross during the war was a social agency, depending for success here on voluntary cooperation. It succeeded. The anti-venereal work in the army was part of a program of health education, depending for success largely on voluntary cooperation. It succeeded, beyond the hopes of its authors, and in spite of the hostility or skepticism of its many opponents.

Are the factors of these successes obvious? If the successful executives named the qualities responsible for their success, could not the heads of work less successful point logically to exactly those same qualities in their work? Yet successes and failures come not by accident. The successful health administrator of the future must be trained consciously to recognize and use those fundamental factors of success now often used unconsciously.

The day when mechanical reforms were the principal health problems is past. The idea of the necessity of a safe water supply has been sold to the people of our towns. Safe sewage disposal has become a prerequisite to a city. The time when the health expert should be merely a sanitary engineer is gone. Even he was dependent upon public sympathy before he could get funds with which to begin his work.

The solution of most of our remaining health problems depends on the successful carrying out of a program of personal hygiene by social engineers, and such a program depends on the cooperation of individuals. Success in health work depends, then, on gaining cooperation. Within the last decade remarkable discoveries have been made of methods of obtaining human cooperation.

The evolution of human thought seems to conform to the Lamarkian theory of physical evolution. Human knowledge has not been accumulated in a series of infinitesimal steps, but rather in spurts, each one accelerating suddenly the growth of the whole body of thought. Such was the discovery of evolution by Darwin and of the circulation of the blood by Harvey. The latest leap in human knowledge is the discovery of previously unknown mechanisms, the understanding of which makes possible the analytical method of psychology. Psychology before this discovery was comparable to physiology in the days preceding our knowledge of the circulation of the blood, when the main basis of physiology was anatomy learned from the cadaver. In the same way our earlier psychology was based largely on a study of brain structure. Analytical psychology deals with the mind in action.

The new theory, briefly summarized, is merely this: Human action more often results from unconscious impulses than from ideas. "These unconscious impulses act like a magnet placed under a paper on which are placed iron tacks. The tacks move when the magnet is moved but the magnet, the force which causes the tacks to move, is not visible."

No attempt to prove this should be necessary, for there is a sufficient and convincing literature; but the best evidence that an awareness of the importance of unconscious measures *pays* is the fact that when these motives are even accidentally appealed to, in dealing with individuals or groups, purposeful and vigorous and effective action results. Later we shall analyze the success, for instance, of the Red Cross in the terms of modern psychology; now we merely outline its principles, and indicate how their application may serve to increase

*The first of two articles on this subject by Dr. Armstrong, to be presented in successive issues of Modern Medicine.

human health. We shall attempt to turn the Freudian complexes into simplexes by using words with their usual meanings attached. With a necessarily arbitrary simplification we shall apply such terms as the unconscious, inertia, repression, conflicts, complexes, disguises, the pleasure of principle, the censor—the main definitions and findings of analytical psychology.

Emotions Energize Action

Action results usually from emotion rather than from ideas. The individual is often wholly unconscious of the motives which really generate his acts. Civilization demands rationalization of action even when the real causative emotion is socially acceptable. Many strong instincts, however, which crave satisfaction are no longer socially acceptable. The individual wants to obtain his satisfactions easily. He cannot obtain satisfaction for his socially disreputable instincts without a conflict with his environment. Therefore, to avoid this conflict, he denies to himself the existence of certain desires. He drives these desires back into the unconscious; but this unconscious personality is a savage. It wants the satisfaction of *all* its desires. It therefore disguises the suppressed desires and sends them back to the conscious, hungry, and ready to do damage if kept unfed. The common disguises hiding anti-social instincts are among the mechanisms discovered by the new psychology. The practical application of this psychology is the conscious appeal to the emotions rather than to the intellect when action is wanted. The many desires variously classed as good and bad can alike gain satisfaction in more than one way. The intelligent utilization of the emotions diverts their energy from useless or undesirable channels and provides for their satisfaction through action which is socially serviceable.

This analysis of the psychology of cooperation is undertaken in an attempt to show how understanding it may increase the success of measures for public health.

Any activity which provides means of satisfying fundamental desires will elicit support. Any activity which ignores or balks the satisfaction of instinct will arouse hostility. There are two parties, the workers and the population at large, whose cooperation and active support is needed in health work. The first, the workers involved, must include everyone from the executive to the members of the most trivial of local committees. The successful program will recognize that the job which offers satisfaction to the greatest number of instincts will obtain the best workers. For a century industry tried to get good work done merely by satisfying the workers' instinct for self-preservation; but hunger is only one motive, and even the promise of its most generous satisfaction does not win the full energy of a man. As a matter of fact, some of the instincts are capable not only of satisfaction but of satiety, and when this point is reached the offer of further satisfaction fails to generate any increase of motive power. The man who will work only three days a week when his wages for that time are enough to keep him for a week is a case in point. His instincts which require imagination have never been stimulated, and so his desires cease with a definite degree of material satisfaction. In most civilized men, however, there are instincts which satisfaction simply stimulates to increased demand. Among these are the instincts for self-sacrifice, praise, power, loyalty, participation, service, beauty and worship. In appealing to groups whose material instincts are with a fair degree of adequacy satisfied, the appeal should be directed to their imaginative or spiritual desires.

Indeed, the reason that the economic motive has loomed so large is not because the instinct of self-preservation is so dominant, but rather that through money we obtain the satisfaction of most of our desires. In lumber camps or places where conditions obtain that preclude the satisfaction of other instincts, such as to love and to play, high wages do not prevent dissatisfaction and the destructive use of energy which invariably follow the balking of instinct. It need hardly be pointed out that it has not been high wages that have procured the full energies of sanitarians and social workers. Their jobs must have given them other satisfactions.

It is comparatively easy to arrange a public health campaign which satisfies many of the desires of the people doing the work. It is far more complex to build a plan which will gain the cooperation of the outsiders, who are the very material of the plan, by offering them means of satisfying their underlying instincts. Perhaps the best single solution is to provide for participation; to give every person affected a job in the health campaign.

Health for Health's Sake Fails

It is certain that the average population, given a knowledge of personal hygiene plus an adequate income, will not necessarily live according to higher health standards. The health for health's sake appeal will fail. Information and opportunity are not enough to inspire the practice of personal hygiene. Look at us! Most of us continue to over-work, to over-smoke, to over-drink (until a recent memorable date), to lose sleep, and to take unnecessary risks of infection. Who are the people in a community who practise personal hygiene? The woman who is proud of her appearance and who is using it, consciously or unconsciously, to captivate the male, will starve herself to keep thin, will exercise when she hates it, and will practise many time-consuming and distasteful rules of hygiene. Why? She realizes that health is a pre-requisite for success at her job. We had in our Army during the war what was undoubtedly the greatest demonstration of personal hygiene ever made by any group. These men had enthusiasm for their job. They had a "will to health" and were willing to undergo the drudgeries of personal hygiene and sanitation for the sake of their work. Our public health problem is to make them as eager to be "fit to live" as we succeeded in making soldiers eager to be "fit to fight."

It ought to be easy to show that health will increase the possibility of satisfying desires, but it is the inherent tendency of men to accept incomplete or imitation satisfactions rather than to expend much effort to obtain full and genuine gratification. Nor does health make the same appeal to different people. The poor person wants health for economic reasons. He cannot afford to be sick. The economic motive in a rich person is satiated. Sickness, rather than health, may serve as a means of gratifying his less satisfied desires to receive additional consideration, and to become the center of his environment.

Dr. George E. Vincent of the Rockefeller Foundation, in a recent address at Johns Hopkins, spoke of the way "patriotic advertising men . . . 'sold' the War, Liberty Bonds, the Red Cross, and Thrift Stamps to the American people . . . by infectious slogans, adhesive shibboleths, vivid posters, and four-minute hypnosis. Certain *motor ideas* were fixed, and held in millions of minds until action was secured." From the means by which they were aroused, motor ideas and emotions seem almost identical.

In the same address, Dr. Vincent suggested that a school of preventive medicine might teach the "art of applied mass psychology, and consciously train men and

women to organize and administer campaigns of popular education in preventive medicine." Might not one, in such a course, asked Dr. Vincent, "imagine complete collections of posters, and other material, prize competitions for new devices and propagandist literature, training in extemporaneous speaking etc.? . . . A fascinating vista opens before men and women of trained intelligence, controlled imagination, and social loyalty," in the field of Public Health.

Knowledge of analytical psychology will aid in developing that "trained intelligence," that "controlled imagination," and that "social loyalty" for health itself, and, also, the practical carrying out of a health campaign must offer fundamental emotional rewards or the structure will be crumbling dust instead of a living, growing thing. First, of course, the health expert must know the instincts needing satisfaction. But this is not a matter of mere cataloguing and memorizing.

The Materials of the Unconscious

Our instincts have been acquired over a long period of time. The unconscious is the common human denominator of us all. It acquires new instincts only after centuries of habitual performance by the conscious self. It does not discriminate between its impulses. Its job is to see that any balked instinct is satisfied. This no doubt is why the sex impulse has been disproportionately emphasized in the popularization of the new psychology, for it is often in conflict with our present moral codes, and so perhaps is most often repressed, thus causing obvious trouble.

But many other motives are in conflict with socially approved values. What desires are forbidden, and therefore result in a conflict, vary in different societies and times. A head-hunter would not need to repress the desire to kill a neighboring chieftain and take his wife. Such a desire would be the extreme of good form for him. But he could suffer as intensely from his tribes taboo on black bass, resulting in a conflict between his desire to conform and his desire to eat, as the civilized man from an occasional hunger for his neighbor's wife, such impulses conflicting with his desire to conform to society's standards.

Speaking generally, however, altruistic motives have expanded while selfish motives have depreciated in the course of civilization. It is, then, the primitive, necessarily selfish, desires which society tries chiefly to balk.

The force expended by the conscious self in repressing disreputable desires, and the force expended by the unconscious in trying to get satisfaction for them, constitute a double stream—a fountain of energy which the successful seeker after cooperation must use. He must recognize that it is only socially accepted motives to which he can appeal directly. The war permitted frank appeals to emotions not previously in good form, but their rehabilitation is not being maintained. The adequate health worker must free himself from the habit of invidious discrimination. He must know that it is as serviceable to divert the energy of a selfish impulse to social ends as to use the energy of the remaining legitimate instincts; but he must take care to cloak the appeal to an instinct of ill repute in the form of an appeal to reason, so that his hearers may be spared conscience conflicts and may continue to conform to the idea that they act rationally.

The etiquette of altruism must also be conformed to. Some of the greatest advances in public health work have been made at the initiative and with the financial aid of commercial concerns, such as life insurance companies and industrial corporations. These agencies, at the demand of the group censor, have displaced their entirely justifiable selfish or economic motive with a correct altruistic symbol. In place of health for profit or for general economic welfare, we have "Life Saving Campaigns," "Live a Little Longer" movements, "Health First Campaigns," "Clean Up Weeks," "Safety First Movements," etc. Thus is the censor satisfied and the conflict eliminated.

The conscious and the unconscious have a common motto: "Anything for a Quiet Life." So the conscious pushes down into the unconscious any desire which quarrels with its environment, and puts a guard at the door of the unconscious. This guard the psychologists call the censor. But the unconscious finds a repressed desire impossible to live with. So it teaches the repressed desire how to avoid the censor and how to go back where it can get what it wants, by disguising itself "very much as the Mexican revolutionist who wants ammunition crosses the border disguised as a peasant woman."

The illustrations which the psychologists cite of these disguised desires seem unsound, on first impression, for the very reason that the disguise is effective. It is obvious that if a nun accosted you in a lonely street and asked for money for charity, it would be important to know that beneath the nun's clothing was the body of a well known gangster. The importance in health work of knowing the common disguises which hide strong motives is equally obvious. For example, an intellectual and reasoned hostility to a health project may be the disguise of an unsatisfied instinct. Perhaps the man who objects to a school lunch on the ground of paternalism is merely concealing from himself his thwarted desire for selfish gain through the renting of his empty store as a lunch room near the new school. It is useless to present reasoned arguments to overcome his hostility. It is worse than useless to tax him with a cause for his hostility which his unconsciousness has disguised successfully in a garment of democracy and self-respect. He may entirely have forgotten the lunch room aspect, and disapproved the whole health and educational program on the ground that it destroys personal liberty and community autonomy. Sometimes an individual will go further than the mere rationalization of his antipathy and will fancy that the program he opposes contains all sorts of attacks upon his integrity or personal welfare. In this stage he is close to a paranoid condition, and will go any length in his vilification of the organization which, perhaps wholly unconsciously, interfered with his selfish satisfaction, in order to compensate for the persecution of which he fancies himself a victim. Unless his condition is too pathological, it may be possible to gain his cooperation by satisfying his desire for gain through modification in some part of the program which may be shown concretely to benefit him. His "reasoned" hostility will disappear, his maldirected energy will become available for the support of a program through which his personal gain may be assured.

The individual who develops such neuroses or psychoses is the neurotic with a characteristic and extraordinary sensitiveness to stimuli. He is the antivivisectionist and the leader in S. P. C. C. or similar activities, whose potential energy for good or evil is greater than that of the so-called normal individual.

There are groups as well as individuals whose inheritance and experience have made neurotic, and their extreme reactions should be considered. Any despised minority group is forced to compensate itself; the osteopaths, the chiropractics, and even some homeopaths still necessarily hate the "old school" far more than the majority

group has sensitiveness to hate or otherwise unfavorably regard them. Disguises are used not only by the individual but by the group. Many organizations are unwilling to sacrifice any of their power or emoluments for the common good. Custom does not permit them to admit their selfishness; so they disguise it by projecting it upon the organization they oppose. In a middle western town there exists an official health body with a conspicuously limited vision, characterized by fearfulness, oppositionism, and vanity. It devotes its vigor to accusing the organization which desires to cooperate of exactly its own pettiness, narrowness, and greed.

It would be both useless and endless to discuss the various instinct-energies which may be directed toward social cooperation. The disguises commonly worn to avoid social disapprobation are well described elsewhere.

The new psychology has a definite part in the equipment of a leader in a democracy. It is easier to direct human activity if one knows its sources. Hostility may be more easily used than indifference, for in the former an emotional connection already exists between the person and the work, and the energy represented by hostility may often be sublimated into a serviceable activity.

(To Be Continued.)

PERSPECTIVE IN DIAGNOSIS OF PULMONARY TUBERCULOSIS*

By MARY JONES MENTZER, M.D., San Francisco, Cal.

THIS study, a presentation of facts derived from the study of one hundred cases, is limited to incipient pulmonary tuberculosis in young working women, who have been under our personal care at Arequipa Sanatorium, and who have been examined by at least three physicians of the medical staff of the institution.

Arequipa Sanatorium, located in the hills of Marin County, Cal., is established to provide at minimum cost the best type of institutional care and scientific treatment for early cases of pulmonary tuberculosis in young wage-earning women.

Each of the one hundred cases included in this study has been analyzed from the standpoint of history, symptomatology, physical, x-ray and sputum examinations, and from these analyses have been compiled the data shown in the accompanying charts.

Scheme of Study

The history, when indicated as positive in the charts, signifies that the patient has had close contact with the tuberculous or has had some of the predisposing diseases, such as measles, whooping-cough, pneumonia, or pleurisy with effusion, or has presented what we have termed a suspicious state, *i. e.*, so-called "fever" or illness often designated by the patient as "malaria," or recurrent attacks of influenza, a tendency to constant colds, or tuberculosis elsewhere.

As shown on Chart IV, 55 per cent of the cases gave a history of exposure, 80 per cent a history of predisposing diseases, and 54 per cent the so-called suspicious state—in all, an average of 63 per cent with a positive history.

Persistent latent râles, or latent râles with dullness, are the minimum findings upon which the physical examination has been designated positive. In 87 per cent of these incipient Arequipa cases the physical examination was positive.

In this series the x-ray plate is rated positive only where the infiltration is peribronchial or is in the parenchyma of the lung. Plates showing enlarged root glands and hilus changes only have been excluded. When it is considered that radiologists generally agree that the hilus shadow is abnormal at an early stage of tuberculosis and also that 125 autopsies at the Foundling Hospital, New York, showed bronchial gland tuberculous in every case, it would seem that our classification of plates has been conservative. The x-ray plates were considered positive in 84 per cent of cases.

The figures indicating positive results in microscopic examination of the sputum cover only the examinations made at the time of entrance to the sanatorium. Twenty of these examinations showed tubercle bacilli.

Klotz[1] tells us that the medical reports of numerous tuberculosis sanatoriums show that in an average of only 50 per cent of cases, including all stages, are tubercle bacilli found in the sputum. Watson,[2] of Mount Regis Sanatorium, Virginia, states that of fifty-nine incipient cases admitted to that sanatorium, only two showed positive sputum after repeated examination. Heise[3] records tubercle bacilli found in the sputum before entrance to the sanatorium in 8 per cent of the peribronchial and in 13 per cent of the parenchymatous types of cases of all stages.

*Read before the Southwestern Tuberculosis Conference, Long Beach, Cal., October 1-3, 1919.

Chart I—Symptoms in Order of Frequency

Loss of weight	91
Ease of fatigue	79
Cough with sputum	75
Chest pain	58
Slight fever	50
Dyspnea	43
Night sweats	32
Laryngeal symptoms	31
Recent Menstrual changes	28
Hemoptysis	28
Cough of more than three weeks without symptoms	23
Gastro-intestinal symptoms	11

Chart I enumerates the various symptoms ordinarily ascribed to this disease and the number of cases in which each was found. Loss of weight proved to be the most constant symptom, occurring in 91 per cent of the series, while gastro-intestinal disturbances were of least frequent occurrence, even less than hemoptysis, which may be unlooked for in view of the fact that we are discussing first stage cases only. Infrequent as the gastro-intestinal symptoms would seem, Cabot has warned us to suspect tuberculosis as a cause of the unexplained indigestion coming in a person who has not changed his diet or his work, who is not anemic or nephritic, or overwhelmed by mental torture or worry. This same authority calls attention to the importance of early hoarseness of voice in the diagnosis of tuberculosis. It occurred in 31 per cent of our cases.

Fever, so often the criterion of the average examiner's diagnosis of tuberculosis, was found in only half of our number and in only 3 cases was it the first symptom noticed in the illness. Osler[4] quotes Reinhold who years ago wrote of afebrile form of tuberculosis, and cited nine of a series of 52 cases as showing no fever. Osler tells of having 18 instances under his own observation, 10 of whom were free from fever. This chart is interesting also in the large number, 58 per cent, showing chest pain, and in the frequency of dyspnea, 43 per cent, as symptoms in early tuberculosis.

Chart II summarizes the result of study of these one hundred incipients with reference to the presenting symptom, or in other words, the first complaint noticed in the illness. Here, as one would expect, ease of fatigue leads, while hemoptysis is least frequently found as the initiatory symptom of pulmonary tuberculosis. Some interesting facts are emphasized by the other components of this chart, *e. g.*, the diagnostic significance of unproductive cough. Cough of more than three weeks duration unaccompanied by sputum occurs in only 23 per cent of this series, and yet in almost all of 18 per cent showing this sign it is the first symptom of which complaint is made. Unproductive cough in nonsmokers should lead one always to suspect tuberculosis.

Chart II—Presenting Symptoms

Ease of fatigue	27
Cough with sputum	25
Cough more than three weeks without sputum	18
Chest pain	14
Loss weight	8
Slight fever	3
Gastro-intestinal symptoms	3
Dyspnea	1
Hemoptysis	1

Again, we note the high percentage of the disease initiated by chest pain, while loss of weight, the symptom most commonly found, is rarely a presenting one. Like fever, it is seldom the initial complaint. Menstrual change, night sweats, and laryngeal symptoms were not noted primarily.

In Chart III we have attempted to reproduce graphically the basis upon which a diagnosis of tuberculosis was made in our own series of cases. It will be seen that in 15 per cent of the cases, all the various diagnostic methods employed were positive; symptoms, history, physical, x-ray and sputum examinations—all were positive. In 63 cases 4 factors were positive. In 60 of these the sputum only was negative, in one the x-ray was negative, in one the physical examination, and in one the history was negative. In 17 the symptoms and history with either physical examination or x-ray were positive. In 5 cases a very definite history of exposure was coupled with symptoms of sufficient significance (Chart I) to warrant the diagnosis of tuberculosis. These are the cases where the subcutaneous or intradermal tuberculin tests are of value.

Chart III—Basis of Diagnosis

Symptoms	History	Phys. Exam.	X-ray	Sputum		
+	+	+	+	+		15
+	+	+	+	—	60	
+	+	+	—	+	1	
+	+	—	+	+	1	
+	—	+	+	+	1	63
+	+	+	—	—	10	
+	+	—	+	—	7	17
+	+	—	—	—		5

It is said that positive factors alone in medicine have an absolute value. The percentage of positive evidence obtained from the various diagnostic methods employed in this series of cases is shown in Chart IV.

CHART IV—RELATIVE VALUE OF DIAGNOSTIC METHODS

Positive physical examination		87
Positive x-ray examination		84
Positive History:		
Exposure	55%	
Predisposing Disease	80%	
Suspicious State	54%	63
Positive sputum examination		20

In the 100 cases presenting themselves because of the symptomatology, physical examination proved of most value in supplying definite evidence of tuberculosis, being positive in 87 per cent, x-ray examination in our work was somewhat less valuable; history was helpful, while the inconclusiveness of examination of the sputum, already referred to, is emphasized by this analysis.

Brown[5] would seem to place the highest value upon the x-ray plate. His comparison of results obtained by physical examination alone with those obtained by physical examination combined with roentgenographic examination shows that the x-ray plate led to the detection of 0.2 per cent more men with tuberculosis than were discovered by careful physical examination. However, we realize that these results were obtained from examination of recruits in whom little if any account is taken of symptomatology or history. Also it is obvious that it is easier to standardize x-ray plates than personal equations in physical examinations. We agree with Pottenger[6] who says that small, early lesions may not always cast a sufficient shadow to be recognized in the x-ray plate, and who concludes that all data found in physical examination when added to the clinical history make clear the nature of the process.

Hawes[7] writes that x-ray evidence should always be subsidiary to a careful and painstaking examination of the patient, his lungs, his history and particularly his constitutional symptoms.

Summary and Conclusions

In making a diagnosis of tuberculosis, especially in difficult instances, one must carefully weigh the many points in symptomatology and history, together with those in the physical examination and in the x-ray plate, as well as the laboratory tests. There is no single positive standard that can be made to cover the diagnosis of pulmonary tuberculosis in every case. It cannot be made from symptoms alone; but even the absence of demonstrable physical signs will not eliminate pulmonary tuberculosis when the symptoms are significant. The x-ray aids in doubtful although possibly not in the earliest cases. The presence of tubercle bacilli in the sputum decides the diagnosis, their absence of course being meaningless; nevertheless it is the combination of both signs and symptoms that is the surest guide. It may therefore be concluded:

(1) That loss of weight, ease of fatigue, and cough with expectoration are the most constantly occurring symptoms of pulmonary tuberculosis.

(2) That ease of fatigue and cough with expectoration are most frequently the earliest symptoms noted in the disease.

(3) That the basis of diagnosis in these cases comprised a combination of symptoms and history coupled most frequently with positive physical examination and positive x-ray plate.

(4) That with symptoms indicative of tuberculosis, physical examination affords the most evidence of any of the various diagnostic procedures.

LOS ANGELES HEALTH ADMINISTRATION

Los Angeles County, California, has adopted a community form of management of joint public affairs that includes the administration of the health departments of its various units. Within the county, with its four or five thousand square miles, are thirty-seven incorporated cities running in population from 500 to nearly 700,000, each of which was formerly independent, with its own machinery for administering its business. With the authority to combine, the county has carefully looked over the different functions, and in those cases where county management proved to be a real economy, has assumed their management. It is now administering such matters as charity, tax collection, public libraries, horticulture, and public health.

Three cities in the county now carry on through the county the work formerly performed by local health officers. It has a number of advantages, among them that of a diminution of multiple taxation that has proved in such instances to be such an economic waste. The county health department now includes a bureau of twenty-six persons besides the health officer. They are employed under civil service rules. The principal office is in Los Angeles, with branch offices established in different places. Cooperation is effected with the school department in the joint employment of nurses. The appropriation, which in all amounted to about $6,000 before 1915, now stands at $60,000.

PROBLEM OF DEPENDENT VETERANS

Dr. W. C. Rucker, chief medical advisor of the Bureau of War Risk Insurance, states that there are 641,900 veterans of the World War who have been discharged from the Army and Navy with disabilities, or who are now under care. The estimated bounty for the care of these dependents is stated to be $325,000,000 annually.

PUBLIC HEALTH NURSING

Industrial, Social, School, and Rural Nursing, Maternity Care, Child Welfare

KATHERINE M OLMSTED, R. N., *Editor*

FEDERATION BECOMES POPULAR

IN JUNE there were held in Chicago meetings of far reaching importance to those engaged in the public welfare service, in which steps were taken to promote the organization of a federation of all national bodies interested in the administrational problems of eleemosynary institutions. At this meeting two national organizations were in joint session, the American Association of Public Officials of Charity and the National Association for the Study of Neglected, Truant, Delinquent, and Dependent Children. Thirty-five states were represented in the registration, and every session was well attended.

The most conspicuous feature of the gathering was the pronounced sentiment in favor of a plan whereby all national organizations in which these officials are interested may meet at the same time and in the same place. A committee of three from each Conference was appointed to give this matter consideration and to submit it to various organizations which might be interested.

Such a plan would simplify the problem, which has become onerous of late, growing out of large number of organizations, a part of whose activities deal with common subjects. Under the proposed arrangement those who want to attend several meetings could do so on the one trip, and all would reap the benefit of the important developments of any meeting, which are largely those of the lobby and the social contact.

The Committee appointed to take this matter up with various organizations has been at work, the idea meets with general favor, and the prospects are that something definite and beneficial will result.

A movement in harmony with this coordination program of the social organizations was manifested by the national health agencies in a conference called on October 18, 1920, at the Red Cross Headquarters in Washington, where a full and intimate discussion of the possibilities of coordination was carried on by the leading health executives of this country.

Dr. Livingston Farrand of the American Red Cross was elected temporary chairman and Dr. Donald B. Armstrong temporary secretary.

The purpose of the conference was to determine the advisability and feasibility of developing more effective cooperation between voluntary organizations engaged in health work. It was the unanimous opinion of the members of the conference that a formation of a National Health Council, whose fundamental purpose should be to coordinate the activities of national voluntary agencies, is eminently desirable and entirely feasible. The object of the National Health Council would be the betterment of health work in the United States, through a close coordination of the activities of the voluntary health organizations of America, and through such affiliations as may not be incompatible with the autonomy of these organizations.

To meet this object, it was proposed that a National Health Council be formed, the charter members of which would be the following organizations:

American Medical Association.
American Public Health Association.
American Red Cross.
American Social Hygiene Association.
Conference of State and Provincial Authorities of Health in America.
International Health Board of Rockefeller Foundation.
National Child Health Council.
National Committee for Mental Hygiene.
National Organization for Public Health Nursing.
National Tuberculosis Association.

It was further suggested that from time to time other voluntary health organizations might be invited to become members of the Council.

The activities proposed for the central organization would include: (1) a central information bureau, (2) a legislative committee, (3) coordination of health statistics, (4) periodic conferences, (5) coordination of state and local health organizations, and (6) the publication of popular health literature.

National nursing organizations have already made effectual steps toward the unification of societies and services, and the three national nursing organizations—the American Nurses' Association, the League for Nursing Education, and the National Organization for Public Health Nursing—together with the American Red Cross, have opened joint headquarters at 156 Fifth Avenue, New York City. They have already instituted a national movement which will continue indefinitely, for the purpose of recruiting students to fill the hospital training schools, and to distribute information relative to nursing education and opportunities open to graduates of the profession.

The coordination of child health activities has been accomplished in the Child Health Council, with headquarters in Washington, under the secretaryship of Mr. Courtenay Dinwiddie.

Workers in the several fields have long felt the need of getting together on the fundamentals of health campaigns. Not only is this indicated in the interests of economical administration, but methods, whether medical or social, need to be scientific and they must be comprehensive. We need everywhere to break down all that may remain of professional aloofness and to work out together the ideals of community service. This is possible only through well planned cooperative effort. EDITOR.

PUBLIC HEALTH WORK FOR COLORED IN THE SOUTH

Contributed by the Department of Nursing, Southern Division, American Red Cross, Atlanta, Ga.

THE subject of Public Health Nursing for the colored people of the South presents some interesting problems which deal basically with the education of the colored nurse doing the work and of the members of her race for whom the work is done.

To the older residents of the South the health problems of the negro have become immensely complicated by modern conditions. During the days before the war between the states there were few problems having any connection with the subject; then it was believed that no negro ever had tuberculosis; few, if any, ever had yellow fever even when it was raging during the most virulent epidemics, and the chief ills from which the negroes suffered were "chills and fever," or what we now know as malaria, and from accidental injuries or natural causes. Of the latter, childbirth may be said to be the main "natural cause," and the percentage of deaths of either mothers or babies was relatively so small as compared with present day rates that it was almost negligible.

Wants a Nurse of His Own Race

In those old days public health nursing was unknown; the plantations of the south were filled with hundreds of negroes in good health, usually, and always directed and supervised by the owners of the land and of the laborers. Quinin, calomel, paregoric, and epsom salts were purchased in gigantic quantities and dispensed with equal liberality. A regular part of the day's routine for the "Marster" was the dispensing of these drugs which delighted the hearts of the negroes. With freedom, came the first inroads of deadly diseases; the wholesome outdoor life of the plantation was changed for the crowded and

These three women are Public Health Nurses, the one on the left a tuberculosis nurse, on the right a nurse in the service of the Metropolitan Life Insurance Company, and in the center a charity nurse with the Collins Board of Health.

unspeakably insanitary life of the cities; poverty, poor food, venereal disease, unaccustomed kinds of labor, all combined to lower the vitality of the negro with the result that for the first years following their freedom they died like sheep and no effort was made to check or change the conditions. Now, the awakened public conscience in matters pertaining to public health necessarily includes the colored with the white population; but, just as it has been determined by experience that the general educational problems of the negro must be solved by an adequate number of negro schools taught by negro teachers, so it is being more and more generally understood that the health

In a physical examination that included seventy children, only these four were classified as normal.

of the negro in his home must be guarded by the Public Health Nurse of his own color. The training schools for colored nurses are most inadequate as to size and enrollment and the supply of colored nurses is therefore limited; so limited, in fact, that few if any of the graduate nurses have been able to take regular courses in Public Health Nursing, and the nurses who have been selected for this work are those whose work will be so closely directed by a supervisor that the actual contact with the family life is the nurse's main contribution to the service.

This has been the method pursued in the South with the negro nurses employed and it has worked most effectively. As a matter of fact, the educated negro of today is markedly lacking in initiative and executive ability, but it is hoped and believed that these characteristics will develop with the added opportunity for the exercise of both qualities.

The colored nurses who are doing public health work for those of their own race are meeting with encouraging success and, while it is recognized that the work is in its infancy, it is worth while to record that the first halting steps are being taken, and that the development of this work will be delayed or limited only by the interest, the enthusiasm, and the support of both white and colored of the communities in which it is being undertaken.

The important part played in all southern communities by the negro cannot be too strongly emphasized. The negro cook, the negro nurse, the negro laundress are all in the closest possible touch with the homes of the South and, with the accepted theory of the spread of disease by contact, the menace of the unhealthy negro as a possible carrier of disease is one that cannot be overlooked, disregarded, or underestimated. It is, therefore, of gen-

uine interest to note the following reports made to the Red Cross by a few of the colored nurses doing public health work for those of their own race, for from these reports it will be seen that the colored people themselves, as well as the colored nurses, recognize the importance of the work undertaken.

Few Colored Nurses Available

In reviewing the situation in Georgia, Florida, Tennessee, North and South Carolina, the five states which com-

This class, 10 per cent under normal weight, are good subjects for nutrition work. A deficit of 7 per cent would be more promising.

pose the Southern Division of the Red Cross, it has been revealed that there are some half dozen colored nurses doing public health work, and that the most active of these nurses are keenly alive to the importance of their service and are anxious to receive any suggestions, instructions or supervision which can be furnished by the states and by the Red Cross.

One of the most active colored services undertaken is that in South Carolina, where the nurse, Ellen Woods Carter, is a registered Red Cross nurse on the staff of Mrs. Ruth Dodd, director of the Bureau of Child Welfare and Public Health Nursing. For the Bureau of Child Hygiene, Ellen Carter has given special attention to the supervision and instruction of colored midwives, for the major part of the childbearing population is served by midwives, many of whom are totally without training and without any understanding of the sanitary rules which childbearing should entail.

Ellen Carter was placed in Beaufort County, S. C., for the purpose of supervising the midwives there and of giving such instruction as was possible. The location of the county emphasizes the necessity for this work, as almost the entire territory is composed of a group of islands—the famous Sea Islands, where the long staple cotton is grown—and the population, because of this industry, is largely composed of negroes. The town of Beaufort is large and has a population of 5,000, of which number only 1,500 are white. Adjacent to Beaufort are the Islands of St. Helena, with a population of five thousand, only fifty being white; Lady's Island, with a five to six thousand population and but one white family; and Pinkney's Island, where unique conditions prevail.

The negroes living on these islands are peculiarly isolated, as there is no fixed method of communication between the islands and the mainland. The women depend entirely on midwives for obstetrical care, and these midwives were of a class whose ignorance was pitiable but whose willingness to learn was touchingly eager after they once understood the need for instruction. The first class which Ellen Carter organized was poorly attended. Only three appeared for instruction, but on this being reported to the local registrar, a police officer was sent out to "round up" the pupils. Soon the class outgrew the class room and the women were eager to receive the much needed instruction.

The homes of the negroes on these islands are clean; the people have good food, and the surroundings are fairly sanitary despite the fact that there are so very few white families. One island—Pinkney's Island—was owned by a Mr. Pinkney, who died some years ago, and his will forbade that a foot of the island ever be sold to a white man or to a negro; that no part of the land be rented to any white man and that the negroes only pay the most nominal rentals. Not a single child's birth has ever been registered from this island, although there is a state law requiring this. Here was a fine field for instruction work, and Ellen Carter made house to house visits, established a regular class of midwives and instituted many sanitary reforms which the people themselves were eager to accept.

To quote directly from a recent report made by this nurse, the following will be typical of her daily work:

Mondays I go twenty-five miles; Tuesdays, five and one-half; Wednesdays, nine; Thursdays, thirteen miles; and Fridays spend in Pinopolis, my home town. At each place I meet classes of midwives; on Mondays I have two midwives classes and two health club classes. Seventy-five women are enrolled in the health club class and each one has promised to go into a home, do a little health teaching, and bring another woman to the class next week. I make it part of my duty to visit schools give health talks, and on Friday and Saturday morning of each week I give bedside care.

To these children, more than 10 per cent under weight, the public health nurse carried the message of proper nutrition as a means of overcoming their handicap.

I find few tuberculosis cases—in eleven months have only discovered four—and these are usually persons who have been away and have come back with the disease. The people live in the open air and in a beautiful section of the state; the homes are clean and, while many have plain board window blinds, these are kept open all the time except when it storms; then it is inconvenient, for you have to sit in the dark until the storm passes.

I have six prenatal patients whom I see once a week, I have them meet in a body and I give a little talk to them and then encourage them to ask all the questions they want. In a single month I have supervised eight deliveries, all normal labor, with eight and one-half to ten pound babies.

Uses Group Plan of Instruction

My plan for getting the women to meet me in groups, either midwives or expectant mothers, is to send a notice to a church and ask the minister to read out that 'the Public Health Nurse' would like to meet all midwives and mothers at a given church at the day and hour announced. The women will come, but are suspicious at first, although I usually win their confidence after the first meeting. First I organize classes of midwives and then health clubs for the women. Our first meeting is closed always with one of what they call their 'spirituals,' which is a sort of song service. I always make it my business to call at the nearest house on my way home from a meeting, and usually I am approached by some member of the class, saying, 'Nurse, you went to Mrs. Blank's last time, can't you come to me this time?'

The best method I have found to approach families is through the children. I meet the children by going to Sunday School and giving them a talk. I then ask them to meet me at a certain place and hour on the following Tuesday, saying, "I have something to tell you," and they come; I never have less than twenty-five or thirty. I find it easy after this to visit the homes of the children.

No children are ever kept home from school for some diseases; whooping cough is one of them, and if you tell the mother that she should keep her children home when they have whooping cough she thinks you are crazy; she thinks you must have something against her or her children. The same is true of measles in the early stages, and it is safe to predict that once a contagious disease breaks out in a community, unless the doctor or the Public Health Nurse gets there first, everybody in the community will get it, because everybody visits the sick; and, if you do succeed in convincing one family that this is wrong, you have done a good day's work.

Transportation is hard for me in my work, and very uncertain. Some days the boats make the trips all right and some days they don't, but I manage to get over the ground some way, and I hope I am doing some good. Anyway, I've given silver nitrate to midwives and shown them how to use it, and have at least convinced them that they may dress the baby before the ninth day without doing any harm to it, and that they MUST take care of the mother, which is a distinct gain.

The children who are only 7 per cent under weight have a safer margin than those showing a higher degree of malnutrition. Once initiated into the proper health habits, they may usually be expected to cooperate fully.

It may be said that this is the report of but one community, but it is an excellent showing and is typical inasmuch as, from the very nature of things, it would seem impossible for the work done by this colored nurse to be undertaken by any white worker. The isolation of the negroes of Beaufort County, S. C., differs from that of other counties in rural districts only in that Beaufort County transportation must be had by water and the other places may be reached over roads the roughness of which can better be imagined than described.

The first stage in undertaking the care and development of the little patient.

Very little public health nursing, however, has yet been attempted for the colored race in the other isolated rural districts and what is being carried on most actively is that in cities where the negroes are herded together in groups. In the town of Durham, N. C., a colored Public Health Nurse is giving full time to the work and her success was so marked that the first nurse who undertook it, Julia Latta by name, was taken over by a famous tobacco company for exclusive work in their plant. Julia Latta seems to be doing industrial nursing along the most approved lines and is evidently demonstrating the need of this service to the satisfaction of the company employing her.

During the work of this nurse in Durham under the City Health Officer, she reports paying as many as four hundred house to house visits in a single month, visiting three graded schools each week, and, when the schools opened in the fall, she vaccinated as many as three hundred children and has given between eight hundred and nine hundred doses of typhoid vaccine in a single month, under the direction and instruction of the health officer.

Houses with typhoid and small-pox were placarded by the nurse, isolation of patients was directed, and special service was given to tuberculosis cases, with a view to placing the patients in suitable sanatoriums, while in many cases material aid was given through the local associated charities and the different church societies, of which there are many all over the South. The relief feature offered by illness and accident insurance companies is also used generally by the colored population of the South, and this is always an effective source of relief during illness of any long duration, which is a great help to the nurse.

In concluding a recent report regarding her past work, Julia Latta said, in reference to her service for the tobacco company, "My work seems to be giving perfect satisfaction. I feel that it is due in part to my previous work along this line and to the fact that I am pretty well known among all classes of people, having been city health nurse for four years and having also been in charge of Lincoln Hospital for eleven years."

From this it will be seen that the value of a colored public health nurse for employees is being recognized by some corporations in the South where colored labor is employed in large numbers.

A colored public health nurse employed by the Jackson, Tenn., Chapter reports that she finds the greatest bar to health work in her territory is insufficient housing for the colored population. She says they cannot be induced to make repairs on rented houses, but that these repairs are badly needed for sanitary reasons, and she urges community action in this particular.

This same need is strongly shown in all cities, and the work of city public health nurses among the colored always comment on this condition. In Atlanta, Ga., valuable work is being done for the colored through the school nursing and the Atlanta Anti-Tuberculosis Association. Charity Collins, the colored school nurse, reports a regular system of school visiting and examination of children by a doctor and a nurse. She describes the approved card given to each child noting its physical defects, and also describes the difficulties with which she meets in inducing parents to have the defects corrected; but she is not discouraged and is working persistently with the children's parents along this line. Charity Collins is a registered nurse. She did excellent work during the influenza epidemic among the white as well as colored nurses. She is a member of the Atlanta Association of Colored Graduate Nurses and is active in improving the standard of colored nurses.

The Atlanta Anti-Tuberculosis Association has put on two full-time colored nurses in the persons of Mary L. Irvin and Agnes Anderson. The city is divided into zones with committees appointed from the colored population, whose duty it is to make house to house canvasses from time to time. By this means it was possible for 143 visistors to be secured and 5,406 colored homes were reached, the number in these homes being estimated at 23,771. Regular educational work was undertaken, talks were given, posters prepared and circulated, letters written, notices sent to newspapers, and the interest of all the colored organizations in the city was enlisted.

During the past year eight clinics were held of four hours each week and seventy-five patients were turned over to the follow-up nurses. An active committee for colored patients has always been a part of the work of the Atlanta Anti-Tuberculosis Association, and through this Committee much effective public health nursing work is being done for this disease which has proven so fatal to the negro in the South.

The principle used by this Association is the only one that can hope to solve the problem—that of using the negro himself as a means of his personal improvement and of betterment for his race. The educated negro is eager to join any association which points to community betterment; the "Public Welfare League" of Nashville, Tenn., which is affiliated with the National League on Urban Conditions among the Negroes, was organized during the war and continues during peace times to give attention to improving the living conditions of the negro and thus to ultimately result in better health conditions.

The Infant Welfare Clinic is the health guardian of the families which come to it.

Health campaigns were conducted at stated times by this League and one of the results directly traceable to this work was the reduction in the city of Nashville of the infant mortality from 202 per one thousand births in one year to 173 per one thousand in the following year.

All of these facts, taken as they are from scattered localities, are mere indications of the beginnings of health work for the negro along the lines of public health nursing. But, meager as the details are, they yet indicate that a beginning has been made and that work in the future will, from all indications, have a normal growth and will eventually result in the permanent improvement of the health and of the commercial usefulness of the colored population of the South.

INFANT WELFARE CENTERS

The widespread interest in the establishment of some form of child health supervision in widely separated communities maintained at local expense creates the need for standards to be maintained in maternity and infant welfare centers. There is published in *Public Health Reports* for July 16, 1920, an abstract from a memorandum in regard to maternity and infant welfare centers issued by the British Ministry of Health, in which modifications have been made by additions and omissions to adapt the organization to American conditions. This publication will be useful as a guide to other communities who are contemplating this type of child health supervision.

INSTITUTE FOR INDUSTRIAL NURSES

The New Haven, Conn., School for Public Health Nursing recently offered a program lasting ten days, including lectures and round tables on public health nursing, industrial nursing, industrial hygiene, industrial diseases, records, ethics of industrial nursing, industrial relations, industrial psychology, nutrition, and health education was offered, supplemented by trips to manufacturing plants and practical demonstrations both in work and play activities.

The institute was attended by fifty-four registered public health nurses, representing eight states. Various industries were represented and the fact was very clearly brought out that, while no fixed rules can be made to fit all places and conditions, certain fundamental rules of industrial nurses can be formulated.

INTRODUCING PUBLIC HEALTH TRAINING IN TRAINING SCHOOLS*

By STELLA FULLER, Extension Secretary, Central Branch Office, National Organization for Public Health Nursing, Chicago, Ill.

LOOKING back over the past fifteen years, several developments which have materially affected our national rural life are outstanding. The rural free delivery of mail has done much for the isolated farm and, incidentally, for the mail order houses; the rural telephone lines have been a wonderful help to the farmers everywhere, making it possible for them to keep in touch with the market reports, with medical help in times of illness, and generally have promoted social life and recreation. Mr. Ford in his manufacture of a cheap automobile has made it possible for parents and children to enjoy many happy times together, and because of it the public highways in this and many other states have been much improved; the moving picture shows, which have such possibilities educationally, are now enjoyed by rural populations.

Along with these helps to happiness and efficiency has come the public health nurse, who until recently confined her work for the most part to cities, towns, and villages. Unfortunately, a public health nurse cannot be secured by a mere expenditure of money. It takes a long time to prepare a public health nurse for the highly specialized work which she is called upon to do. We must face the fact that for a long time to come we cannot expect to have enough public health nurses to do the city work, to say nothing of the rural districts, where it is so badly needed.

Need Cooperation of Training Schools

One of the most effective ways of combating the shortage of nurses is the opportunity this shortage affords to encourage the interest and cooperation of superintendents of training schools, whose function it is to make the public health field attractive to their students.

Here it should be stated that all nurses should be public health nurses. I once made the statement at a nurses' meeting in Washington, that all superintendents of tuberculosis sanatoriums are or should be public health nurses, and a very able nurse questioned the statement, though it should be plain enough that no sanatorium executive can deal humanely, intelligently, or well with poor, discouraged tuberculosis patients unless she knows the principles of public health nursing and sees their great opportunities.

There are about three thousand schools of nursing in the United States. The hospital is the laboratory of each school. The extent of the task of educating the students is appreciated when we remember that their preparation should include a study of all the phases of health and sickness. Someone may say: "It is not necessary, or advisable to provide public health training for a nurse who intends to specialize in surgery or possibly laboratory work." Why not? The surgical nurse should know that the operative case might never have needed to enter an operating room if the forces of public health working together had reached him. She should know the kind of home to which the patient returns, the food provided for him, the care he is to receive, the kind of job he gets, as all these factors influence his future physical and mental welfare.

All are familiar with the term "complete maternity protection," which means "careful guidance and education of the mother before the child is born, good obstetrical care during the lying-in period, constant follow-up work until, and *after*, the child has reached adult life, in order that posterity may be benefited." The obstetrical nurse who simply takes a case for ten days or two weeks has an experience similar to that of a theater-goer who sees only the second act but knows nothing of the first and third.

It must be conceded that student nurses should have some instruction and experience in social service, in school, child welfare, industrial, tuberculosis, mental hygiene, and visiting nursing.

Wisconsin Problem Stated

The problem for Wisconsin is: How is this extra training to be provided? Who is going to pay for it? Should it be included in the present three year course, or should the time be made longer? Is four months time sufficient for a public health course? Where, in Wisconsin, can the necessary field work and supervision be provided? Should there be a special instructor or director? Should this extra work be attempted by supervisors who perhaps already have all they can do? Is it expected that the students after graduation will be on a par educationally with nurses graduating from recognized courses in public health nursing? Would it be best done through the close cooperation of nursing schools, visiting nurses, or public health associations and a college or university? Should it or could it be done in a uniform manner throughout the state? Is the new hospital at Wisconsin University planning to include such a course? Is it not possible to send such pupils to Milwaukee to take a course given by the Wisconsin Anti-Tuberculosis Association? If public health nursing is included, will anything now included in the training school curriculum be shortened or omitted?

Situation Demands Added Facilities

It is certain that public health nursing should not be introduced in a training school that is already poor. No public health nurse can do efficient work if her training lacks the necessary experience in children's diseases, obstetrics, and related fields. Some schools have thought that they could secure probationers more easily if public health nursing was offered. Nothing in a training school course should be omitted to make public health nursing possible. The public health nurse needs a careful, well rounded course.

What Any Superintendent Can Do

Every training school can do some things, however, to interest and educate pupils in public health nursing. The superintendent of nurses can see that current numbers of the *Public Health Nurse*, a magazine devoted to public health nursing, is always on the nurses' library table; she can see that the National Organization for Public Health Nursing poster is somewhere in sight. She

* Read before the annual meeting of the Wisconsin State Nurses' Association, Wausau, Wis., October 3, 1920.

can arrange to have the pupils see moving pictures showing the work of public health nurses. The National Organization for Public Health Nursing has a film that can be rented for five dollars per day, plus transportation charges. Bibliographies, reading lists, and pamphlets on public health nursing can be secured for the hospital library. The Joint National Committee of the American Nurses' Association, National League for Nursing Education, National Organization for Public Health Nursing, and the American Red Cross, also offers a series of prepared lectures on public health nursing to be read to student nurses by an authorized public health nurse.

The prepared lectures cover achievements and opportunities in the field of public health nursing; visiting bedside nursing; industrial nursing; prenatal, maternity, infant and child welfare nursing; tuberculosis nursing; nursing in the venereal clinic; medical social service; mental hygiene and the public health nurse in relation to community development. The lectures have been written by nurses who have had many years of experience in the public health field and it is hoped that every superintendent of nurses will arrange with a local public health nurse to give these lectures, supplemented by her own experience, to the entire school. The little booklet in which the talks are printed will be sent gratis from the Central Branch Office, N.O.P.H.N., 116 S. Michigan Avenue, Chicago. Each booklet is numbered and is to be returned after the lectures have been given, in order that they will not be used after the material is out of date.

These lectures have been read by the Educational Committee of the National Organization for Public Health Nursing, Miss Anne Strong, director of the school of public health nursing conducted by Simmons College and the Boston District Nurses Association; Mrs. Bessie Haasis, who until recently was the Educational Secretary of the National Organization; Miss Katherine Tucker, superintendent of the Philadelphia Visiting Nurse Association and ex-president of our Organiztaion; and Miss Hudson of Teachers College, New York City. Miss Elizabeth Fox, Director of Public Health Nursing under the American Red Cross and Miss Mary Marshall, Supervising Nurse for the National Tuberculosis Association, are members ex-officio of the Educational Committee by virtue of the fact that they are "consumers" of public health nursing.

In several large cities—Chicago, Boston, Philadelphia, and Los Angeles—the superintendents of training schools have arranged to have the senior students of several schools meet at a central place for a series of ten lectures on public health nursing given by different nurses who had studied and worked along special lines.

For the past three years Mrs. Theodore B. Sachs of the Chicago Tuberculosis Institute, 8 South Dearborn Street, has arranged a series of lectures for senior students of accredited schools. The course for this season consists of twenty-five lectures to be given by social workers, physicians, and nurses of Chicago. The students are brought together in three groups, because of the number of pupils and distances in the city, making it necessary for each instructor to give the same lecture three times. Outlines of the talks are given to the schools in advance, and at the end of the course each student prepares a thesis on one of the subjects. The papers are marked by a committee and prizes awarded. The distribution of literature might very well be added as it would assist the students to get a better idea of each subject and it would, of course, be valuable for reference.

Miss Jane Hitchcock and Miss Suzanne Haliburton in New York City, have visited many training schools to speak on public health nursing.

In April, 1920, the Henry Street Settlement, New York City, made an interesting report of an experiment in preparing under-graduate nurses for public health nursing. Thirty-six hospital training school pupils were sent to the settlement for a period of four months, from the Newton Hospital, Massachusetts, the Presbyterian, the Post Graduate, St. Vincents, and Bellevue, New York, and from the Army School of Nursing. They took three courses at Teacher's College on the principles of public health nursing, home-making, adjustments in social work, and the principles of modern social work, the class work being supplemented by actual field work.

The expense of maintaining the students was met, for the most part, by the hospitals from which the students came. The total expense of students from the Army School of Nursing was paid by the Red Cross. This was because the army regulations would not permit the Medical Department of the army to meet the expense. According to Miss Goodrich, on present schedules, the complete expense of the students so admitted is about four hundred dollars for the student for the four months, not including the overhead expense of supervision, etc.

In one month, 6,490 visits were made by these students. Of course, much time was necessarily spent in group and individual conferences. It was first thought that each student should have her own district as is arranged for the regular members of the staff, but it was finally arranged that a student should be under a regular member of the staff who would give her such cases as would afford the most complete and valuable experience.

These student nurses wrote their impressions of the course afterward. They were all impressed with the gratitude, trust and appreciation of the people whom they served,—and it is to be remembered that many of these New York district patients are immigrants who do not speak the English language. The student nurses said they had heard that such living conditions existed, but they did not believe it until they went into the field and saw the background of patients who, in the hospital, were only cases.

Student Impressions Significant

A student nurse who was very enthusiastic concerning the public health work she had in Cleveland, said she enjoyed every minute of it. She liked the home visits, the lectures, and the demonstrations given in the class room. She had chosen the public health experience because she wanted a broader outlook on the nursing profession. Her final decision was: "Knowing some of the problems the public health nurse has to meet, I am convinced she should have the wisdom of Solomon!"

This young woman would have little patience with the nurses who *want* to do public health nursing, but refuse to spend time and money to prepare themselves for it, many such applicants claiming that they *know* they can do it because they get along well with people, or that they served overseas.

Adds Interest to Training

One who knows has said: "The pupil nurses who take this work not only acquire some knowledge of public health work before graduation, they also carry back to the remainder of their hospital course a knowledge of the environment of their patients which shows them their work in a greatly broadened aspect. Moreover, many of them become so interested through this brief glimpse of the public health field that after graduation they wish to specialize in it."

Our Educational Committee has made the following sug-

gestions for the guidance of superintendents who contemplate including public health nursing in the training of nurses:

(1) Not less than two full months, including theory and practice, should be considered—four months time is preferable. At least eight months are now considered necessary for a complete course in public health nursing.

(2) At least six hours of theoretical instruction should be given weekly.

(3) The instructor in theory and practice should be a public health nurse of considerable experience who can *teach*, not simply take the nurse with her.

(4) Not every pupil in the training school can be given this experience. The superintendent should decide which pupils should have it.

(5) The students should work with an experienced nurse for a considerable time, at least two weeks, before being permitted to make visits alone.

(6) The Association responsible for this training of the pupils should not give it with the idea of *getting work done*.

(7) Definite arrangements should be made to finance the pupils during the time they are away from the hospitals. (The Red Cross has paid Visiting Nurse Associations sums of money in this good cause, now the hospitals are doing more of it.)

(8) It is better in making plans of this sort to have the pupils spend the whole time getting experience in one phase of work, such as tuberculosis nursing, or bedside nursing, rather than have them get a smattering of all, with no clear idea of any.

(9) Such experience is not to be considered a course. It simply gives the nurse a broader, more intelligent idea of health and disease, and prepares her for work on a staff where she can have careful supervision.

There are about 150 hospital training schools in the United States giving this training to their pupils now.

The Philadelphia General Hospital and the Jewish Hospital of Philadelphia are sending their pupils to the Philadelphia Visiting Nurse Association. An outline used by Miss Frost in this work, can be secured through the New York Office of our National Organization for Public Health Nursing, 156 Fifth Avenue. In Boston the Massachusetts General Hospital, the Peter Bent Brigham, and the Quincy Hospitals are cooperating with Simmons College and the Boston Instructive District Nurse Association. In New York the Post Graduate, the Presbyterian, and the Newton, Massachusetts, Hospital, and others have been giving their pupils the benefits of Teachers College and Henry Street Settlement. In Cleveland the Lakeside Hospital, the City Hospital and Mount Sinai Hospital are sending students to the Cleveland Visiting Nurse Association. The Chicago School of Civics also took student nurses up to the time the school was discontinued a few months ago. More complete lists and further information can be secured by writing Miss Anne H. Strong, 561 Massachusetts Avenue, Boston, Mass.

Finally, to quote Miss Nutting, who said in a paper read at the Atlanta meeting: "A serious weakness with which we have to contend lies in the character and amount of teaching provided for student nurses. There is urgent need of better work in this direction, of a wider range of subjects more *thoroughly handled*, better equipment in the way of classrooms, laboratories, and libraries; just such provisions, in fact, for teaching as are commonly found in all other professional schools."

If there be almost no constitutional disease in wild nature, why should it persist in mankind? Why should man and his stock have a monopoly of senility? If certain microbic diseases can be got rid of, why do we allow them to linger in our midst? . . . If we cannot alter the span of human life, we can at any rate make sure what we shall *not* die of.—Thomson.

HOME HYGIENE CLASSES POPULAR

By Miss Mary D. Collins, Chicago Chapter, American Red Cross

THE Chicago Chapter of the American Red Cross, through their Juniors, have in the last year given in the public schools a practical course in Home Hygiene and Care of the Sick. This course has been given during school hours and credits have been allowed the children for the work. The course was first started in seventeen elementary schools with the approval of the Board of Education in the seventh and eighth grades. It met with such universal success that it was put into eighteen more schools, one of these a high school, and at the same time a trial course was started in one of the parochial schools of the city. This course was taught by a registered Red Cross nurse, carefully selected with attention given to her ability to teach children. An ideal equipment was shown but the lessons were given with substitutes such as would be found in any home. From an entirely different angle the children were taught how to take care of themselves, how to prevent disease from spreading, how to care for the sick; how to keep a chart, to take temperature, to make a bed; and how to wash, bathe, and feed a baby. The success of this course has been remarkable. Teachers told of whole families whose personal appearance in cleanliness had been changed after the child had a few lessons. During the recent epidemic doctors and visiting nurses remarked upon the efficiency of the children in the homes where this course had been given. Many a mattress that had never been turned has now been shaken vigorously and a properly made bed is the pride of many of the children. Between four and five thousand children have had this course, with the result that the parents of these children and the teachers in the schools have asked for a course for themselves. It is impossible to estimate the value of this course or its wide-spreading influence. Universal interest was aroused in these very essential matters that have to do with every day home life and by this means whole families were made alive to their health needs.

In addition, the same work has been given to several thousand adults throughout the city, the classes being carried on in community centers, schools, and churches. Many of the classes have been among the foreign born and it is felt that the work takes an important part in the plan for the Americanization of these people.

Plans are being laid for more extensive work in this field next year and many thousand women and children will thereby be made better mothers and home-makers.

USE CARE IN WORKING CERTIFICATES

A warning to parents was issued recently by the State Department of Labor and Industry, New York, calling attention to the provisions of the School Attendance Law, which requires that before obtaining a working certificate, the child must be certified by a physician as sufficiently sound in health and physically able to perform the work the child intends to do. The order states that the purpose of the requirements for health certificates for children is to safeguard the child entering industry, to shut out from industry children with such serious defects as to make their employment dangerous, and to protect children from entering occupations or processes for which they are physically unsuited. The object of the law is defeated unless the examination is distinctly related to the work the child desires to enter. Examining physicians are enjoined to acquaint themselves with the general nature of the occupations which the children in their districts desire to enter.

PROBLEMS IN SOCIAL MEDICINE

Medical and Health Education, Child Welfare, Social Insurance, Rehabilitation, Medical Law and Allied Subjects

JOHN A. LAPP, LL.D., *Editor*

THE CHURCH AND SOCIAL HYGIENE

AMONG the resolutions passed at the recent Lambeth Conference of Bishops of the Anglican communion, according to the *Survey*, was a plea for cooperation in the suppression of venereal diseases, a definite stand against the use of venereal prophylactics, opposition to birth control by use of contraceptives, and a statement of the necessity of furnishing proper sex instruction to children.

The Conference, moved by responsible statements from many nations as to the prevalence of venereal diseases—bringing suffering, paralysis, insanity, or death to many thousands of innocent as well as guilty—supports all efforts which are consistent with high moral standards to check the causes of disease and to treat and, if possible, cure the victims.

We impress upon the clergy and members of the Church the duty of joining with physicians and public authorities in meeting this scourge, and urge the clergy to guide those who turn to them for advice with knowledge, sympathy, and directness.

The Conference must condemn the distribution or use, before exposure to infection, of so-called prophylactics, since these cannot but be regarded as an invitation to vice.

JULES SCHEVITZ.

FEEBLEMINDEDNESS AND TUBERCULOSIS

THAT physical diseases have psychic effects and mental diseases have physical effects are generally conceded. An interesting attempt by Menninger[1] to assign a definite and clear cut relationship between tuberculosis as an example of a physical disease, and feeblemindedness as a representative of mental unhealthiness, serves to illustrate the necessity for a broad attack on tuberculosis as a public health problem.

With a steady development in the tendency for modern medical specialization, Menninger rightly reminds the specialized health worker what the latter has consistently urged on school administrators in discussing child health, namely—a consideration of the physical as well as mental aspects of child life. The body as well as the mind goes to school, and neglect of the body will be reflected in the child's mental progress. So in the case of physical disease in which psychic effects are manifested, and in mental diseases in the presence of physical derangements, it becomes necessary to study the problem with both the mental and physical ailments in view.

Tuberculosis as an effect of feeblemindedness is by no means infrequent, and the same applies to venereal diseases. It is obvious that in such cases that the treatment of either the physical or the mental condition demands a careful consideration of the other. The fact that these ailments—physical and mental—are often associated and arise out of similar social situations makes the interrelationship even more striking.

A recent study by Brown[2] of the social and medical aspects of childhood delinquency indicates a definite relationship between the child's physical deficiency, such as improper nourishment, and the mental condition. With improvement of nutrition, hyperactivity and irritability have been noted to disappear. Special examination in mental health as well as physical is essential for prevention. Social attitudes toward conduct disorders have served to prevent rational treatment.

"Look at the whole patient," is Menninger's plea. "Ill fares that man, or his patients, who conceives them as carrying their lungs in one basket and their brains in another." If feeblemindedness is at the root of many social ills, including tuberculosis and syphilis, the mental hygiene worker is performing a definite contribution to the anti-tuberculosis and social hygiene programs. The health worker on his part can render a material service in the mental hygiene movement by referring mental deficiencies to the proper agencies for expert attention.

JULES SCHEVITZ.

BIRTHS SHOW INCREASE

In the birth registration area of the United States exclusive of Rhode Island, which failed to send in transcripts of birth certificates, 1,365,585 infants were born alive in 1919. The total number of deaths in the same area was 791,732, the births exceeding the deaths by 573,853, or 72.5 per cent, these figures affecting about 58 per cent of the total estimated population.

The number of births for the year 1919, compared with 1918, shows a decrease of 7 per cent in the registration area. Each state shows a decrease, the percentage ranging from less than one in Maryland to ten in Utah and Wisconsin. This is in marked contrast to previous years, as the number of births had increased from year to year.

The infant mortality rate is 87 in 1919 and is the lowest infant mortality rate on record in the birth registration area. Among the states these rates range from 63 in Oregon and Washington to 113 in South Carolina.

COORDINATION FOR CHILD HEALTH

By RICHARD A. BOLT, M.D., Gr.P.H., General Director, American Child Hygiene Association, New York City

THE National Child Health Council, a council of national organizations for coordinating child health activities, has opened headquarters in Washington and begun its work as a first active step toward that coordination in the health field which has been desired for a number of years by nearly everyone engaged in health work. The Council has secured as its Executive Secretary, Mr. Courtenay Dinwiddie, who brings to this important position exceptional qualifications and a wide and varied experience.

The earlier stages of the wider application of biology, medicine, hygiene, and philanthropy to the amelioration of disease were marked by isolated efforts in special fields by the proponents of one measure or another.

It was natural that the borders of what one considered his special province would overlap that claimed by another. Life does not recognize our nicely drawn classifications, but ever requires to be met by properly adapted, correlated efforts.

The interdependence of the innumerable factors of disease has developed the interdependence of organizations for relief. Learning, research, and administration are all served by a program which brings individual effort into essential harmony with cooperative planning, which brings each individual observation to bear collectively upon the intelligent handling of the entire problem.

It is significant that this advance in practical health coordination was stressed at the Eleventh Annual Meeting of the American Child Hygiene Association recently held in St. Louis. Dr. Philip Van Ingen, the retiring president of the Association, in speaking of the need for cooperation, said: "We should be willing and anxious to accept good methods proposed and tried out by other organizations and preach them as part of the general program. It is only by a knowledge of the work of other organizations on our part, and their knowledge of our work, that we can pull together and conserve our energy. We are an army—an army of construction; it is only by unity of action and complete cooperation, which must be based upon complete knowledge of one another's plans, that our constructive warfare will end in success."

All Problems Are Interwoven

At the same meeting Mr. Herbert Hoover, in laying out a national program for child health said in part:

All the problems of birth, health, food supply, education, labor, and housing are so interwoven that they must march step by step. . . . We need more widely extended teaching of the fundamentals of nutrition in the public schools, not only as a part of the advance in public health but also in household economics. Some may object that this extension of medical supervision by community nurses, clinical inspection of children in schools, a supplemental meal in schools of certain sections, all tend to an extension of too intimate government. In the very creation of free schools and compulsory education itself, we have accepted the fact that we cannot as a Nation rely for the upbuilding of the race upon the initiative of the parents alone. No one can deny that the physical development of child life is of equal importance with education. We, every one of us, pay the price in our jails, in our poorhouses, in our hospitals, in the loss of our economic efficiency, the fertile ground that we furnish for all the social patent medicines, for our failure to have grasped the entire problem of child development, not only intellectual but physical as well. . . . Every child delinquent in body, education or character, is a charge upon the community itself. The children of strong physique, of sound education and character, are the army with which we must march to progress.

Our conception of social problems and social needs has developed in such a piecemeal fashion as greatly to increase the tendency toward a high degree of specialization in health work for children, as in other social fields. As soon as anyone conceives a new idea to meet some problem which he believes has received inadequate attention, his inclination immediately is to develop a special program for that particular problem without attempting to relate it to the programs of others. The obvious result of these tangential efforts has been a very serious lack of correlation, both in local and national efforts, and in many cases overlapping and duplication.

It is scarcely an occasion for surprise to find three or more organizations preparing and issuing literature on the same subject, such as, "How to Organize a Baby Clinic," "Child Health Centers," etc. The several statements are often based on wholly different standards. Such a diversity of views, particularly among those who are looked upon as authorities, causes great confusion in the minds of field workers, to say nothing of the ordinary citizen. It was with this in view that the American Child Hygiene Association made a careful study of the programs of all national organizations purporting to carry on any phase of child welfare. This was followed by the preparation of digests of the programs of sixty-four national organizations which were compiled and distributed to the various organizations. Is it any wonder that the business men, when appealed to for funds, have said, "there is no end to these organizations"?

The officials of a city, because of a contact established at a conference, or in some other way, may issue a written request for the services of a representative of a national organization. That organization may be unable to meet this request and yet it may be entirely possible for a representative of another organization to meet the demands at just that time and place.

There is no more well known result of lack of coordination in the health field than the fact that nearly every organization has members of its staff, as individuals or as expert librarians, going over a mass of periodicals, books, and literature generally, digging out information of one sort or another of special interest to that organization. There is certainly a great opportunity for common helpfulness through a pooling of efforts in this field alone.

A Clearing House of Common Helpfulness

It is only recently that we have begun to find that these more or less obvious defects through lack of coordination are far less important than the very serious gaps in our health program, which exist because of lack of common planning. There is a general and increasing demand all over the country for a really well rounded program for child health.

The representative of that national organization who is called in to advise in the establishment of one or another of these activities can no longer escape the respon-

sibility for presenting not only his own particular problem and its solution as he sees it but for telling the whole story of a generous and vigorous program for the positive health of a community. A specialist, whose expert opinion on infant feeding as a community problem may be sought, should not even tacitly leave the impression that the feeding problem is the whole problem and is settled for life in early infancy.

After a number of years of preaching community coordination, some few communities are actually beginning to practise a genuine subordination of individual interests and correlation of effort for the common welfare.

How can national organizations sincerely and effectively act as advisers to local communities if they do not begin to set their own house in order and practise the same spirit of genuine correlation of effort that is being demonstrated in some of the more progressive communities?

With these things in mind, five of the national organizations with well defined programs, devoting their efforts wholly or partially to child health, have decided that it is time for action to try out some of the possibilities for common planning and coordinated effort. The five organizations that have thus joined hands in forming the National Child Health Council are the American Red Cross, Child Health Organization of America, National Child Labor Committee, National Organization for Public Health Nursing, and the American Child Hygiene Association. It is expected that before long the National Tuberculosis Association will join the Council.

The main objects of the Council, briefly stated, are:

1. To define and develop so clearly their own work that each organization will be working in harmony and cooperation with all the others.
2. To develop new methods which will lead to meeting more effectively some of the special problems still unsolved.
3. To afford an opportunity for any organization dealing with the health of children to submit its plan and program for suggestions.

Acts as an Advisory and Coordinating Agency

The Council has decided that there are two main lines along which its program of coordination may best proceed. The first move will be toward securing a consensus of authoritative opinion on some of the general problems of policy and also on special medical, nursing and other questions relating to child health. This will be the first step toward agreeing upon common objectives.

As a means to this end, it is proposed to create national advisory committees on special subjects. The membership of these committees is not to be limited in any way to membership in the Council, or in the organizations which so far make it up. It is planned to have these committees as broadly representative of authoritative opinion and experience as possible, so that they may serve all who wish their advice and help.

One of the next steps the Council will have to take is to see that these committees have sufficient help in order that they may really be active and useful. For the present, the burden of this will probably fall most heavily upon the five organizations which have joined in forming the Council.

Another definite line which the Council proposes to follow is that of actually trying out coordination in field work. Many possibilities suggest themselves and it will be the duty of a sub-committee to determine which are the most practicable and to see that genuine effort is made to try each out thoroughly under the best possible conditions of cooperation.

It is natural that a movement of this kind should center around the health activities of the child. That is a field in which people surely can be drawn together. It also happens to be a field in which five of the organizations with fairly well defined health programs for children are keenly interested in seeing such coordination brought about.

The most interesting thing about this endeavor is that it has been entirely spontaneous within the organizations themselves and not due to any outside pressure. Other organizations will undoubtedly wish to come into the Council as it demonstrates its usefulness.

A NEW "AUTOMAT" IN LONDON

Keystone View Company.

The new automat installed in London makes it possible for late customers to help themselves. The contrivance for dispensing the milk is fitted low into the door of the dairy, well within the reach of the smallest messenger. The presence of a "grown-up" is unnecessary.

LESSONS IN MOTHER-CRAFT

More attention should be paid in schools to instruction in the elements of hygiene, and all senior girls should receive lessons in mother-craft. No scientist would hand over to an uninstructed girl a delicate piece of scientific apparatus, and expect her by some natural gift of intuition to know how to handle it, control it, and use it. But, by habit, that is what we are daily allowing to occur. Girls of all classes marry without the haziest ideas as to child-nature and child-welfare. It is therefore little to be wondered at that the proportion of babies which die in the first year of life is enormously high, especially in our great cities. Many of these unfortunate infants are first babies. They die that through their unavailing tears their inexperienced mothers may acquire some slight knowledge of how to rear children.—*Mackenna.*

PRESENT TRENDS IN MEDICAL PRACTICE*

By FRANK B. WYNN, M.D., Indianapolis, Ind.

The strength and weakness of medical practice, whether general or special, are mere matters of attitudes, of personality applied to the problems involved in the new adaptations now demanded.

If the general practitioner lose faith in his method, his work slumps, and he is in a fair way to become a part of the present disorganization.

If the specialist unduly narrow his range of vision, if he corner the special methods of technic and daring modes of treatment, his spectacular course will too often be marked by noisy plaudits.

When schools turn out, first, men; then thoroughly prepared general practitioners; later on, specialists; and, last of all, a fully coordinated service which handles the patient as a reacting mechanism instead of a bundle of unrelated disorders—the new ideal will have been evolved.

SPECIALIZATION is the key which unlocks the door to modern progress. The world acclaims its virtues and extols its achievements. In every avenue of human activity specialism prevails, no less in commerce and manufacture than in science and art. Thankful for its rich fruits of benefit, it should also be our duty more often to inquire if there are not perhaps at the heart of the system, subtle and undermining influences which may threaten the foundations of civic life.

By intensive effort in a limited field and the economic advantages of labor division, specialization may reveal wireless telegraphy, produce a marvelous machine, and bring luxuries within the reach of all; but do we stop to think of the multitude who become mere unthinking cogs in the wheel of industry; who grind their lives away without initiative; whose hearts do not pulsate with the joy of their work; whose single thought is to produce quantity and receive the wage? On the one hand, division of labor, cheaper production, and larger dividends for the corporation; on the other hand, organization, unionization, and larger wage for labor. The goal held up is not contentment in life, joy of labor, perfection in workmanship—but how well will it pay? It is pertinent to ask if medicine has shared this world wide trend toward materialism. If so, let us beware lest our profession degenerate to the level of a trade.

The Propaganda of Special Medicine

Medical specialism has grown with phenomenal rapidity. Beginning a few decades ago as a mere tributary of the main stream of medical practice, it has swollen to a flood and the question is where will it end? In its earlier history the so-called proprietary medical colleges were the most potent influence in spreading the propaganda of special medicine. Under the newer régime in medical teaching conditions are improved, but the curricula and clinics still give special branches a dominant influence. The truth of this statement is evinced by the fact that rarely does a medical student graduate without resolving upon a specialty, at once or in the near future. By him specialists are grouped as a class of the elect in medicine; general practice he looks upon as the recourse of the mediocre and unambitious. He views general practice as a sort of purgatory for the abandoned in medicine, from which sphere now and then one may be translated to the realm of the blessed in specialism! And now has come the World War, inundating the country with specialists of high and low degree! Lastly, the State has gone into the specialty business; but it opens up a new problem it is not our province at this time to discuss.

The triumphs of specialism have been the chief glory of the profession. It is a record dazzling the eyes of the world with its brilliancy and swelling the heart of mankind with thankfulness. In the realm of pathology alone, it has yielded knowledge of the causes of disease and laid firm the foundations for modern triumphs in medical and surgical practice. It has made plain the field and revealed the methods for tilling the soil in preventive medicine. No less amazing have been its achievements in the practical branches of the profession; but let not this brilliancy blind us to the existence of corroding agencies which may eat at the vitals of our profession.

From the very outstart medical specialism has exhibited a virile aggressiveness somewhat at variance with traditional medical modesty. The specialist feels impelled to write or talk about his subject upon every hand. The profession in general has condoned the practice, although with occasional mutterings. In medical society the votaries of specialism are quick to proclaim its virtues. Medical journals unstintingly spread its propaganda. Almost every mail brings the reprint, which we are sometimes disposed to consider obtrusive. So long as this aggressiveness is scientific and not commercial in bent, we should welcome it with open arms. Such, in the main, are the contributions of specialism. Along with these virtuous efforts there creeps in all too often the spirit of arrant boastfulness, constituting the bad manners of specialism. Who is not familiar with titles like the following: "My First Hundred Operations for Ectopic Pregnancy," or "Analytical Study of Three Hundred Successful Appendectomies"! The observant practitioner listens with rapt attention, but subtracts liberally. The latter may be courted by good manners; he is more likely to be won by straightforward, scientific presentation; only seldom is he duped by arrant boastfulness.

Sharp Contrasts Are Made

During this period of growth in specialism, the general practitioner has gradually sunk into the slough of despondency. He comes to look upon his specialist colleague as one always dwelling in Elysian fields and reaping rich fruit with a minimum of effort. Sharp contrast is drawn between the labor and rewards of the specialist and himself. Avarice eats at his heart. Envy comes to sit with him, where formerly abode faith, hope, and courage. Viewing from afar, he gets a distorted impression of the specialist's life, which he pictures as always in the midst of flowery beds of ease. He weighs his own sacrifices—his sleepless nights, his hastily swallowed meals, his meager fees, and belated vacation against the imaginary ease, the smug and thrifty appearance of the specialist whom he meets. He coddles his conscience into the conviction that something is fundamentally wrong. Dangerous ground this upon which he is treading. He is in imminent peril of sinking into the mire of materialism.

*Presidential address before the Forty-Fifth Annual Meeting of the Mississippi Valley Medical Association, Chicago, October 26-28, 1920.

Here arises the degrading impulse to enter into partnership with equally sinful specialists in the secret division of fees—a practice wholly at variance with the idealism of the profession. Thus has grown out of specialism the nefarious and unprofessional practice of rebating and fee-splitting,—a thing which is material, mercenary, dishonest, and shocking to the medical conscience.

The disparity alleged between the net income of specialists and general practitioners is more apparent than real. Rather a wide acquaintance with both groups warrants the author in the deduction that more general practitioners than specialists amass comfortable fortunes. It is curiously true that specialists seldom finish their careers full handed. This is explained in part by the relatively shorter fastigium of the specialist's active career. He is always obliged to spend liberally in keeping up appearances. He belongs to expensive clubs; maintains offices of considerable pretention; employs expensive assistants; drives a fashionable automobile; and lives in dignity comporting with one of rank in the profession. Much time is devoted to preparing medical papers and attending medical meetings. His professional prestige makes him a favorite target for subscriptions to charitable undertakings with a medical bearing. He gives largely of his time to medical teachings and attendance upon dispensary and hospital clinics. Thus is he, no less than the general practitioner—although in a different way—kept in constant turmoil and anxiety and his career has more of the gamble in it than the steady gait of general practice. True the general practitioner receives smaller fees, often outrageously small, but his earning career extends over a longer period; the source of his income is more stable; the customs of his practice beget the habit of frugality; he saves and invests wisely.

Instead of condemning specialism for elevating the level of fees, the profession in reality owes it a lasting debt. A deservedly higher standard has been set toward which we should all strive. Competition in all special lines has become so acute that no longer does the charge of a money-making class hold as in the halcyon days of a few decades ago.

In this connection it is but fair to say that the surgical specialist enjoys a monetary advantage over his less spectacular colleagues, the internist, the laboratory man, or the general practitioner. To the average layman, an amputation, a herniotomy, or the removal of an ovarian cyst possesses heroic appeal, however simple the mechanics of the procedure. He pays a liberal fee for the operation without quibble. On the other hand, the quieter methods of diagnostic or therapeutic procedure seem to him commonplace, though they may require the most skillful technic and in their interpretation call for the exercise of the finest judgement—decisions, in fact, upon which hang life and death or the determination surgical action. Yet at the exaction of any considerable fee for such service the layman expresses astonishment. In cases where courts determine what constitutes reasonable remuneration, judges and juries are likely to award liberal allowances for surgical operations, but reduce other fees to the dead level of a unionized scale.

The public is greatly in need of enlightenment upon what constitutes proper valuation of professional services —whether laboratory, medical or surgical. The layman needs to be taught that the practitioner who carries him safely through a siege of typhoid fever or pneumonia, with their perilous risks, has performed a service as large as a surgeon who removes a cyst from the abdomen or drains the gall bladder. Systematic cooperative attempt is needed to bring about the proper readjustment of fees.

Turning from this critique of the economic phases of specialism, I wish to consider a trend toward materialism, which is of a wholly different nature. In its very essence medical specialism means restriction of effort to a limited field which is intensively cultivated. The specialist becomes a piece-worker, prone to forget the body as a whole, just as the piece-worker in the factory becomes an automaton, uninterested in the machine of which his part is a unit. The deadening effect of piece-work upon the intellectual and moral fiber of the laborer is a psychologic factor which employers recognize has a large bearing on the labor situation.

To a limited extent the same thing is true of specialism in medicine. Its trend is toward materialism. First, it has taken out a large number of physicians from general medicine, and assigned them to limited fields of thought and practice. The lay world has noted the change with sadness in a few instances, but has not yet awakened to the seriousness of the situation. The family physician had become an institution in the community. He was bound to his clientele by the indissoluble ties of affection, confidence, and confession. Let us grant that he knew less of the intricate mechanism of the body and its functioning, but acknowledge him as gifted in the study of the individual as an entity—his heredity; his endowments and weaknesses; his reactions to physical and mental stresses. These things he knew first hand. How different his from the specialist's viewpoint. One makes a lifetime study of the individual as a whole; the other takes a momentary glance at a limited area—at substance, a thing, an organ, and not the coordinated, functioning organism as a whole. Specialism sees tubercles about the ureteral orifice, or notes the "choked disk" of brain tumor; clarifies a situation by a positive Wassermann or discovers by the x-ray an operable cancer of the colon. How fine it all is! Let us give full credit here where credit is due. But it is just as certainly true that the specialist, in his hot pursuit for cold facts, loses ardor for the sentimental, moral, and spiritual elements of man. He develops hypertrophic mentality along special lines but atrophy of spiritual and moral sense for the sacredness of the human body and human life. Too often the goal sought is ambition,—a new method, a record on operations, or a consuming desire for volume of business; this, rather than service as a physician, ministering to the comfort and happiness of mankind in the healing or alleviation of disease.

The specialist who achieves large business success is in grave danger of becoming narrow and self-sufficient. Who would dare question his opinion, so superior upon his special subject? Counsel would only jeopardize the patient's chances. To his way of thinking, what general practitioner would have the temerity, for example, to suggest that a tonsillar operation be postponed in view of a rapid heart, suspecting blood stream infection; or that tachycardia in a patient with enlarged thyroid might be due to incipient pulmonary tuberculosis; or again that pain in the McBurney area might presage an outbreak of pneumonia? In some this self-sufficiency may become arrogance, as conceited and offensive as in the ignorant rich. This type of man is prone to boastfulness in the matter of his reading and study: "I have no time for anything except my specialty," is his vain and self-satisfied assertion. His type is exceptional but too prevalent.

On the other hand, there are a considerable number of special men who seek in every posible way to enlarge perspective. The eminent surgeon, Nicholas Senn, was such. Often in the course of his lectures or clinical presentations he was wont to pause rather dramatically, saying: "The

surgeon is a *physician* who operates." His implication, of course, was that he had no patience with the narrow special man, and that the real surgeon must have breadth of view, comprehending the whole field of medicine. Three or four years ago another surgeon of distinction spoke to me of post graduate studies he had been making. In reply to my remark that I supposed he had devoted himself entirely to his particular field of abdominal surgery, he replied: "O no! I took laboratory courses and work in physical diagnosis." This man, an ex-president of this Association, is beloved throughout the country for his fine spirit, his sterling character and his great ability. Toward his sick-bed of invalidism the whole profession turns to salute a hero,—a man four-square and measuring up to the highest ideals of specialism.

Science Consistently Humble

Whether we accept the Biblical account of the Creation or not, it cannot be controverted that man ranks first in the creative order. The human body is the most wonderful temple we know about—a house not made with hands. It is, therefore, a sacred temple. For centuries past this has been the idealistic conception of medicine. What matters it to us, if it be the body of a pauper or millionaire, saint or sinner, Negro or Chinese, idiot or seer—to us it bears the divine impress. Before this shrine we bow, as true physicians, with humility and reverence, taking no account of age, social status, or mental condition. To us life, human life, becomes a sacred thing, whether *in utero*, in the mature individual of amazing complexity and power, or in the aged seer, rich in achievement. All alike command us to reverent duty as custodians of the earthly tenement and its occupant! With such a conception we are not likely to tear down that which we cannot build up; and we shall view wanton mutilation of the body in the name of surgery as criminal.

In this connection it is pertinent to ask if the advent of asepsis and improved surgical technic has not ofttimes led to forgetfulness of these truths? The prevailing opinion of the layman is that we *do forget*. A brief historic review of surgical evolution during the past four decades will offer convincing evidence that the charge is true. Too often we have displayed the common human weakness of yielding to fads; despising the old simply because it *is* old, forsaking the steady light of proved knowledge for the glare of a rocket shot into the professional sky. Thirty-five years ago what burdens of offense were charged to the ovaries! These organs were sacrificed and mutilated for neuralgia, neurasthenia, hysteria, dysmenorrhea, epilepsy, and insanity; and to what end? Woman was robbed of her greatest function; her body was deprived of an important internal secretion; and the diagnosis ultimately shifted from the surgeon to the neurologist.

Following closely upon this procedure has come the appalling multiplication of abdominal and other major operations, many of them imperative, most of them justifiable, but a considerable residue unwarranted if not criminal. It is rather disheartening to those of thoughtful mind to observe the insidious hardening of the medical conscience; to note the haste and lightness of thought with which major surgical attack is advised and undertaken. Very often not even time is taken for painstaking study of the patient from every angle. Instead, a short-cut method is pursued. "We will open the abdomen and see," expresses the unscientific procedure followed. It becomes our bounden duty to inquire if perhaps there is not at the present time an orgy of surgical excess? Everywhere hospitals, everywhere surgeons, many of them excellent, some indifferently equipped, others bad! Already in the wake of this surgical excess are appearing unfortunate sequelae, sure to increase in the near, oncoming years. No one appreciates this more fully than the abler specialists themselves. For the correction of this trend there must come to everyone essaying to do major surgical work a new baptism of reverence for the sacred human body. Let every specialist get out of the rut where he sees only the special part or thing, and look upon the man—the pulsating, reacting, thinking man with a human soul!

Must Standardize the Specialists

The public, long insistent upon specialism, is now awakening to the fact that it is not an unmixed blessing. Generally, the layman acknowledges great benefits from its wise ministration; but on the other hand he occasionally runs the gamut of specialists, isms, and cults; drifting from uncertainty to uncertainty, with waning confidence and depleting purse. Finally, in dire extremity he exclaims: "O, for a Doctor! An old fashioned doctor! One who is willing to get acquainted with my family, learn their weakness and idiosyncrasies; ready to serve them by day and by night; able to treat them for typhoid fever, pneumonia, and measles; a man to whom I can tell my secrets and not be afraid!"

To this bewailing appeal let it be said with assurance that "the doctor of the old school," the physician who treated every malady to which flesh is heir, is gone, never to return. Beloved of memory and idealized in literature, he served well his day and generation. We note with sadness his passing and may seek to revive many of his virtues. Modern progress insists upon a new and better order, which is being wrought out through specialism. Since it is a product of human effort, it is but natural there should be some of the faults of human weakness. But with all its shortcomings naught will hinder the triumphant forward march of specialism.

With the rapidly changing conditions of the industrial, commercial, and civic world must come corresponding changes in the methods and requirements of our professional life. To meet these in the proper spirit and work out their solution with intelligence and justice is a paramount duty at this time. Several important agencies are already engaged in trying to remedy present evils. Splendid advancement has been made by the State Boards of Medical Registration in raising the requirements for medical practice. The Council on Medical Education of the American Medical Association performed a noteworthy service to medical education in elevating the standard of requirements for medical colleges. Similar effort now being made to standardize hospitals is a move in the right direction. The National Research Council is reaching out for cooperative effort from general practitioners and specialists in the study of clinical, statistical, and other problems of practical and scientific interest to the profession. The scope of influence of these various organized activities is necessarily limited and does not afford the protection to the public which it has a right to expect. Some method must be devised for a more inclusive standardization of those worthy to be classified as specialist.

It would seem that in the near future the State must assume the responsibility for those qualified to practice in special fields.

Any critique of specialism is incomplete which does not reckon fairly with the general practitioner. It is sad but true that the advent of specialism has cast a shadow of despondency over the man in general medicine. He is obsessed with the feeling that he has descended in the

scale of professional prestige and esteem. Before his imagination there passes in vivid review the memory of sleepless nights, of jaded nerves, of piteous appeals from poor, and arrogant demands from the rich; of things he would read pushed aside by things which must be done; of belated vacations and of thankless, thoughtless clientele turning from the family doctor with indifference to shout the praises of specialism. When asked by the stranger if he is a specialist he replies apologetically: "No, I am only a general practitioner." What has come over the spirit of his dreams? Wherefore does he thus indulge in self-depreciation? Why have others less worthy, perhaps, and less serviceful, marched past him with flying banners, receiving the world's acclaim while he has remained behind, a pack-horse carrying the impedimenta and bearing the chief burden in the heat of the day? What can be done to save the general practitioner from himself,—for his own sake and for pressing community needs as well? How shall he adapt himself to the changing conditions of the time; how keep pace with the progress of specialism?

First, he must be brought to the realization that his job, rightly performed, carries greater responsibilities and offers larger opportunities than any specialty. At the present time he does not believe this. How can the fact be brought home to him? The truth should be inculcated early in professional life. The province of the medical education should be to produce high grade general practitioners—not specialists. The latter are a later evolution. Specialists will make themselves. Eradicate from the minds of students the idea that any sort of preparation will suffice for general practice. Here, of all places, training should be thorough. History-taking, clinical observation, and physical examination must be developed by the student to the degree of a fine art. These are the indispensable instruments with which the general practitioner hews a way through the entangling forests of signs and symptoms to the open plain of light and truth. Why cast them aside for short cut methods in diagnosis? When used rightly, they yield information generally more important than the microscope, the test tube, the guinea-pig or the x-ray. The woodman were as wise to cast aside the axe, with the assertion that he will clear the forest with a chisel and auger.

In the next place, there needs to be developed among general practitioners an *ésprit des corps*,—a loyalty and solidarity of effort for mutual betterment. There must be the increased mingling of those engaged in general practice which begets enthusiasm, clinical alertness, and scientific morale. In this way will be aroused a consciousness of the magnitude and dignity of the work, and a pride in the accomplishment of its great tasks.

In the future advancement of the profession, general practitioners and specialists will cooperate more fully one with another. The old idea of professional exclusiveness and selfishness is rapidly passing. The medical society has led the way. Medical men need only to be brought together to prove that their interests are mutual and not antagonistic. *That* man is apt to be a poor doctor who has not as his most trusted and beloved friend *another* doctor. This spirit of goodfellowship is becoming manifest all over the country in the assembling of physicians' offices in the same building; or in the more intimate association of men in groups. Special and general men are associating themselves not so much for financial reasons as to study medical problems in common. The phenomenal success of the Rochester Clinic has given tremendous momentum to this idea. But human nature and varying human capability make the plan impossible of universal application. Insuperable difficulty lies, first, in the securing of men adequately prepared in the respective fields; and, secondly, in the uncertainty of harmonious adjustment in determining the relative expense and remuneration of the group members. Complex partnerships are prone to end disastrously. More likely to succeed is a simple partnership of two or three who assume the burden of financial responsibility and management, and who are willing to pay liberally for the services of specialist associates and technicians. The group plan will prove highly successful in a few instances. More frequently it will fail because of professional, financial, or temperamental incompatibility of the members. In the very nature of things, only a small number can ever come under such a régime.

The Benefits of Contact

In a larger way what leaven may be planted in the greater professional mass that will finally leaven the whole lump? There must come a more intimate association of practitioners. The medical society has accomplished incalculable good in this direction, but its benign influence must be multiplied an hundredfold. For example, what fine professional advantage would accrue if all physicians of accredited standing in a smaller city had their offices in the same building; if they maintained in common a comfortable room in which were housed a good library containing the best medical books and journals, an attendant and telephone—a center of friendly rendezvous where it would be customary to meet often; to listen to reviews of recent medical articles of unusual nature; exhibit cases, demonstrate specimens, and technical methods! Out of such friendly association should grow naturally the impulse to study in a cooperative way many problems.

In the past, data upon which professional knowledge is based have come largely from public institutions. Why should not that much larger clientele *who pay*, also contribute to the common fund of medical knowledge? Having different environment, is it not true that careful investigations will probably reveal different results? Conclusions drawn from such observations, if systematically and carefully carried out, will tell more accurately of things as they actually exist in practice than institutional investigation. The study of epidemiology; occupational diseases; problems of hygiene and public health; of work in relation to the cause and cure of cardiovascular disease and tuberculosis; of diet in Bright's disease and diabetes, but give an inkling of investigations which might be undertaken by the general practitioner, if the work were promptly organized and directed.

A problem of especial interest to the general practitioner has arisen from the multiplicity of expense, from special examinations often necessary in obscure cases. Patients of ample means may run the gamut of specialists without protest; but to the man of moderate income the expense becomes prohibitive. The latter makes up the bulk of the general practitioner's clientele. They are worthy and are entitled to thorough diagnostic study. For their relief the State will in the near future be forced to maintain thoroughly equipped diagnostic clinics. Whether our private interests will it or not, he is indeed blind who does not see that such is the inevitable trend of public demand. Twenty-five years ago private laboratory workers made cultures for diphtheria, stained sputum for tubercle bacilli, and urethral pus for Gonococci. A little later the Widal test for typhoid, the complement fixation test for tuberculosis, and now the Wassermann for syphilis—all at first private enterprises, now are

taken over largely as public functions. The wide range of diagnostic usefulness of the x-ray with its charges prohibitive to the man of ordinary means, will compel ultimately the establishment of public x-ray laboratories where only a nominal charge will be made. These evolutions are working a hardship to private laboratory workers. The public, however, will not concern itself with the interests of a small class. Its slogan will be the greatest good to the greatest number. It ill becomes us as intelligent professional men to behave toward these changes with reactionary vehemence. Rather let us gracefully accept the trend of events, adapting ourselves to the changing conditions and directing their course.

This brief review of the trend toward state medicine is given to show what should be its bearing upon the general practitioner. Here soon will be placed at his disposal most of the technical, diagnostic procedures. He will be spared their tedium and escape the expense of their maintenance. Nor does this signify that his work will be less dignified or important.

His business will be to correlate and interpret the findings; to look at each disease problem as a whole—the causative factor, the clinical course and the measures to induce prevention, amelioration or cure. He will have more time for reading and study of cases. Awakened conscience and duty will require it. The public have a right to demand it. The specialists and technicians of the public clinic who will furnish the data for his consideration are his lieutenants and captains; he must be the general to direct and command. His position is the one of chief responsibilty and honor. He should be able to judge wisely of the material submitted. He will study the map of the individual's life, pointing out where in the past physical defeat has been suffered and where, in the future, foes will lurk. It will be for him to direct the course to pursue and indicate where reinforcements will be needed in the battle against disease. Such is the dignified position which the general practitioner of the future must occupy if medicine lives up to its traditions and fulfills its ideals in the future as it has done in the past.

Service Has Its Rewards

Lastly, it should be noted that in this age of pressing commercialism the general practitioner has been prone to forget the chief recompense for his sacrifices and drudgeries. Upon the altar of self-denial and service to his fellows he burns out selfishness and narrowness of spirit. Behold eternal friendships and undying gratitude, no less from those high in the walks of life than from the most lowly; from the joyously triumphant as well as from the sick at heart and those bowed low with grief. His heart pours out unceasingly in sympathetic and helpful ministrations. This his greatest opportunity, his greatest reward—a reward which comes seldom to the specialist. The latter thus misses one of the finest privileges of professional life. Its absence is apt to beget in his nature a cold, selfish materialism which drags him to the level of a tradesman bidding for business. This the gravest danger of the specialist from which he must save himself.

Fraternity is the watchword of the age. The tocsin of war upon selfishness was sounded nineteen hundred and twenty years ago. Although the world has often wavered from the ancient exhortation, it has been shaken to its senses by the greatest war of history. The terrible conflict, with its immeasurable sacrifice of treasure and countless human lives, has brought a little nearer the brotherhood of man. The second lesson of the World War is that in union there is strength and that by sympathetic and loyal cooperation great achievement results. In the profession of medicine a splendid past cheers our hope and nerves our courage for a more glorious future. True to the traditional ideals of our profession, let us, like the knights of old, train every unit in preparation for the battle against disease. Troops of general practitioners and troops of specialists there must be, but all are of the medical army to which we owe allegiance.

CAN HEALTH BE TAUGHT?

This pertinent question has been recently asked and answered editorially by the *New York Times*, in whose opinion the fact that campaigns to that end seem paradoxical to some is probably because of the imperfections of the human mind.

It is our custom to regard physical ills as a subject for deep sympathy, and moral lapses as deserving sharp reprobation. In the far and fabled land of Erewhon, as readers of Samuel Butler's satire will recall, the situation is precisely reversed. A banker who had been detected in embezzlement received flowers and visits of condolence, and was otherwise made much of, quite as we treat an invalid. But amid these festivities he caught cold, whereupon he was bundled off to a dark room, and his afflicted household was gravely perplexed to find an excuse to shield his iniquity. If he had been discovered, he would have been sent to jail. The point of the satire is plain. Weakness of character and moral obliquity are largely hereditary; they can sometimes be ameliorated, but never wholly removed. Bodily health is for the most part subject to control. People who are wise in their eating, sleeping and exercise have daily use of their maximum strength and are virtually immune from diseases of infection.

The campaign of the Bureau of Education, now being waged in Washington, D. C., is directed primarily against malnutrition. The child's weight and height are recorded and compared with the development which has been determined as normal for his age. Complexion, blood, circulation, and breathing may be likewise recorded. As applied to early infancy, the process is well known to modern mothers, and the only occasion for wonder is that it has not hitherto been continued in childhood and adolescence.

Health teaching has proved to be a powerful ally in the teaching of hygiene, and its results are more immediate and practical. Children, like the rest of us, are easily interested in themselves and quick to appreciate the improvement which a little care will make in their good looks, well being and efficiency. *School Life*, the organ of the Bureau of Education, devotes the current number to an account of the growth of the new movement, its methods and achievements.

STUDY CAUSES OF LONGEVITY

A study of persons who have lived to be seventy years of age or more has been undertaken by Benzion Liber, M.D., D.P.H., 61 Hamilton Place, New York City, with the purpose of discovering the cause why their lives have been longer than that of the average man, and in the hope that conclusions may be reached which will help in the prolongation of the life of others. The collaboration of physicians, public health officers and social workers is desired. Those sufficiently interested in health conservation to give this matter some of their time whenever they meet an old man or an old woman will be supplied by Dr. Liber with copies of his questionnaire.

PRESENT DAY SOCIAL HYGIENE PROBLEMS

By LEE ALEXANDER STONE, M.D., Surgeon (R), Regional Consultant, United States Public Health Service, Chicago, Ill.

THE time must come in the affairs of men and women in this country when a single standard of morals will exist, and anything which will interfere with putting into force such a standard should meet with the disapproval of those who feel that the greatest thing, after all, is the conservation of the race in order that a greater and mightier civilization may grow out of the present.

To return to the original matter under discussion. Syphilis, like its brother, gonorrhea, unless carefully treated, may destroy; syphilis is more deadly to the human economy than gonorrhea because its virus may penetrate to the most remote corners of the body. No disease known to man is as capable of as much physical destruction. It may attack the nervous system and produce locomotor ataxia, or cause hemorrhage in the brain of the young man under forty and bring about paralysis, or cause paresis—softening of the brain. All of these conditions are produced by syphilis alone. Rotting ulcers of the body, decay of bones, even to the extent of producing deformity through their being eaten entirely away, are the frequent results of a failure properly to treat this disease. These effects are noticeable on the individual who has failed to take treatment after having contracted the disease either through illicit sexual union, or through the use of a dirty drinking cup, face towel, razor, or shaving brush used by a syphilitic, or sometimes through inheritance.

If the effects of syphilis stopped with the individual first infected, and treatment could be administered that would be curative, all might be well; but, unfortunately, curative measures require years of administration, and syphilis may be transmitted to the next generation born after the one in which the sower of wild oats had his fling. To go through maternity hospitals where hundreds of babies are born yearly and there witness the mark of this scourge on the bodies of the innocent children who should have been born with a clean heritage and inherent strength from their parents, should be enough to force strong men and women into a fight that would have as its goal the whipping of venereal disease.

Of all syphilitic children, 80 per cent die within a few days or months following birth, while of the remaining 20 per cent, many die before they reach puberty, and those who live usually become weaklings either mentally or physically. Inherited syphilis is one of the major causes for idiocy, and many a girl who offers her body for sale on the streets is what scientists call a moron, or a high grade idiot, she having inherited in most instances from a syphilitic ancestor causes for the mental deficiency that made her a moral delinquent.

For the benefit of those who may doubt the statement that the average prostitute is feeble-minded, the following statistics should prove helpful:

Chicago Morals Court:

639 habitual prostitutes examined.

85.8 per cent feeble-minded.

104 sexually immoral girls in Illinois Training School for Girls.

97 per cent feeble-minded.

Massachusetts Vice Commission:

300 prostitutes examined in three groups of 100 each.

1. Young girls just beginning.
2. Street walkers.
3. Old offenders.

50 per cent of all were so mentally deficient as to warrant confinement. They came from degenerate families.

Massachusetts Reformatory for Women showed that out of 243 women examined in connection with history of commercialized prostitution in their care—

49 per cent defective mentally.

16½ per cent very dull.

Out of the remaining 84 women, 47 had other defects: epilepsy, hysteria, and psychopathic defects.

15 per cent normal appearance.

Bedford State Reformatory. Dr. Katherine B. Davis reported a study of 647 prostitutes:

29.8 per cent feeble-minded, 20 of whom were classed as insane.

107 distinctly feeble-minded.

193 insane or insane tendencies.

New York Probation Association. Of 500 delinquent girls:

37 per cent mentally defective.

Illinois prostitutes under same care:

35 per cent mentally defective.

26 per cent (included in above).

35 per cent feeble-minded.

Massachusetts Reformatory. Dr. Edith R. Spaulding reports:

205 sex offenders.

50 per cent mentally defective.

40 per cent segregable to prevent propagation of undesirables or degenerates.

Psychologist of Massachusetts Reformatory for Women, Dr. Catherine Brammick, reports:

Of 260 women admitted in eleven months, 178 were for sex offenses.

Of the remainder, practically all have been guilty of sex offenses, but were committed for other crimes, as drunkenness, larceny, etc.

149 committed as prostitutes.

42 per cent of these readily classed as feeble-minded.

A. F. Treadgold says, "My experience is that about one-half the girls admitted into Magdalen Homes on account of first fall are feeble-minded."

Social Service Department of Michigan Department of Health, Detroit. Report of Josephine S. Davis:

60 prostitutes arrested.

21 feeble-minded.

13 subnormal.

1 feeble-minded and defective.

1 epileptic.

3 insane.

8 paranoid trend.

2 psychopathic.

11 non-psychopathic.

Eleemosynary institutions of one type or another—jails, penitentiaries, insane hospitals, homes for the feeble-minded, etc.—are all monuments erected to the wild oats sower, and in them their inmates may trace in most instances the causes for their incarceration to inherited or acquired syphilis, which, while though not actually producing the discrasias of the disease itself, leaves a weakened brain or body.

An Awakening of the public conscience is necessary if this country is to overcome the effects of venereal diseases. *Unless something is done, and at once, syphilization will replace civilization,* and the citizens of this nation will become decadents totally unfit to carry on the affairs of state or to breed a race that should have in its blood an inherent power sufficient to make itself felt the world over.

The World War has made this country a world power. No longer will the United States be able to sit back complacently and speak of its isolation. Her sons, by their valorous actions on the fields of France, proved to the world that a new and vigorous type of manhood was to be found in the nation that boasted of its broad democracy.

A new democracy was born out of the womb of War, a democracy that really teaches brotherhood. Across the seas, where men fought and died together, no question was raised as to caste or to the possession of wealth; the one qualification asked for and demanded was an ability on the part of men to stand up and deliver. The man who delivered the goods, whether he was the son of a washerwoman or the scion of a house of wealth, was the man most sought after. So it is today, the man or woman who can do the greatest good for society and who can stand up and deliver the goods is the one society is looking toward to bring about the change that must come and make order where chaos has been.

Ignorance the Blighting Curse

Education must be more sought after than it has been in the past. More attention must be paid to the developing intellects of children and of young men and women. If instruction along lines of social and sex hygiene was of aid in making the United States Army of four million men the healthiest and the strongest in the world, certainly the oncoming generation will be benefited by similar teaching in order that it, too, may be strengthened and forewarned and forearmed against the deadliest menace known to man. By proper instruction of the next generation it will be prepared to give battle to the evils of darkness and drive them into the light of day, where they may be viewed and treated accordingly.

Children must receive a type of instruction that will enable them to know better how to overcome the possibility of falling into error. Ignorance is the blighting curse of humanity. Ignorance with regard to the powers of reproduction has sent many a girl into the dark chamber of despair (she would have been spared had her parents been honest with her), to be kicked and stoned by a mob who, had it met the Nazarene, would have cringed under the same rebuke He uttered to the one which brought before Him the woman who had sinned. "Let him who is without sin among you cast the first stone at her." No men or women can ever throw stones until they themselves have been purged by the fires of knowledge and have become teachers of new ethical standards.

Children should not be answered with a lie when they ask questions, but should be told the truth in a plain manner that will cause them to have a wholesome respect for that which called them into being—the reproductive impulse.

If the parent instructs the child in a proper manner and the child goes wrong, it may do so deliberately, and the father or mother will feel no need for self-blame. On the other hand, if the parent does not instruct and the child errs, then the blame may be placed on the shoulders of the ones who should have safeguarded the child by eliminating the curse of ignorance from its life.

It should be the proud boast of parents that they have so thoroughly instructed their children in the vital things of life as to cause them to know that if ever they are tempted, their chances of falling will be minimized. If daughters who are to be the future mothers of the race could be made to see the reason for their demanding clean bills of health from sweethearts who may propose marriage to them, again would there be a reduction in the causes for racial decay. Men should feel proud of women who would ask for a guarantee of good health from them. These women would be fulfilling in the greatest measure natural laws that define motherhood as being that something which, when brought to the highest development, will give to the world children with a promise of becoming greater beings than the mothers or fathers who called them into existence.

High minded citizens and scientists are fighting for better babies. Better babies can be born only through the exaltation of motherhood and fatherhood. Only through the inforcement of a single standard of morals, and the development of greater ethical standards for men and women in their sexual relationships, can the future salvation of the race be guaranteed.

Just so long as racial poisons are allowed to permeate the warp and woof of the fabric from which civilizations are made, just that long will weaklings be born who can never expect to forge ahead and make this Country the greatest nation in the world. Not until the things mentioned before have been put into practice will society see the elimination of the wrecks lust and licentiousness have made of those who have lived lives of sensuality and contracted disease in the living. Just so long as women are considered the lawful prey of men and are made to become prostitutes in order to gratify the lustful appeties of brutes—prostitution being a man-made institution and the human family the only one wherein even a semblance of prostitution exists,—civilization will remain at a standstill, and such after results of venereal disease as early insanity, perversion, degeneracy, mental aberration, and other mental and physical defects will be apparent, and racial decay will stalk through the aisles society has made for it through the neglect of those fundamental principles enunciated by nature.

Every year, in the autumn, fairs are held in different states in the Union. Pedigreed animals of all kinds are shown and valuable prizes given for the fine physical qualities they are capable of displaying. Not one of the animals shown but has a long pedigree; his dam and sire are known to have been bred right, and the process of fine breeding may be traced back in some instances six and eight generations.

The United States Department of Agriculture spends millions of dollars yearly bringing up to standard animals and plants, and its published reports are full of the results obtained through selection of the fit and the elimination of the unfit. If such things are possible with animals, why are they not possible with humans? Why cannot men and women be brought to see the advantages of bringing into the world more children of quality?

Must Look to Our Lineage

If the more intelligent men and women would look around them whenever they leave their own homes, they could not help seeing on the streets the many hopeless and helpless beings whose pedigrees may be traced back to degenerate ancestors. It is not an unusual sight to see a poor mother, who is not only ignorant and illiterate, but apparently mentally deficient, with four or five weak and puny children hanging onto her trying to lead them

along. No attention has ever been paid to her ability to breed a type of offspring of which society should feel proud; she is merely a machine of faulty construction capable only of developing faulty material to reflect discredit on her. No attempt is ever made to aid her to improve herself and her surroundings. She is regarded as being an unfortunate and consequently is forgotten by society. Those who go into the slums of a great or small city usually draw their skirts aside from those poor individuals for whom they themselves are responsible. There they see nature at its lowest ebb and shrink from it.

Attention must be paid to the rearing of children, and men and women in whose bodies lies a cause for racial decay must not be permitted to call into existence beings who are bound to become a drag on humanity. Men and women who are unfit should be sterilized.

Homes for the incarceration of the feeble-minded must be built, and all morons and those suffering from weakened mentalities, that make them unfit to fight life's battles, should be placed in them. These individuals should be sterilized at once, in order that their seed might not bring forth a weakened offspring.

As has been intimated before, the only way possible for the present generation to win its fight against venereal diseases and their attendant terrors will be by education of the public to familiarize it with all the dangers of syphilis and gonorrhea; the education to be left in the hands of sane medical men and equally sane laymen and laywomen who at heart are more interested in the future of the race than they are in dollar gain and in inquisitorial methods of reform.

To carry education to a fitting conclusion, those suffering from venereal diseases must be made to see the advantages of medication and long treatment. To this end there must be established clinics where those who cannot afford to pay for treatment from specialists may receive it free. These must be manned by competent individuals who are entirely familiar with the treatment of gonorrhea and syphilis, and who are at the same time able to inspire the confidence of the patients attending these clinics, in order that they may carry to others a knowledge of the careful treatment they are receiving. A clinic to be properly run must inspire confidence; patients attending it must be made to feel that everything known to medical science is being done for them, and that the end in view is to develop them into good citizens again as free from disease as treatment will make them. Hospitals, wherein men and women infected with venereal disease may be sent and detained, must be built in order that treatment may be forced on those who are careless.

The United States Public Health Service, in 1918-19 and to July, 1920, through an appropriation made by Congress, was able to give every state in the Union that has laws looking toward the treating and quarantining of venereal diseases, sufficient, which, when doubled by the legislatures of the states, made it possible to carry on a vigorous fight for the control of gonorrhea and syphilis. This appropriation will be continued until July, 1921.

"The distinction between today in action and the days gone by is that the unit is no longer the sick man, but the community and the people affected—or likely to be affected—considered as a whole. We do not mean that the individual is disregarded. We do mean that the regard had of him does not stop within the confines of his sick-room, but envisages him rather as a risk, a focus of conflagration—than a cause. It is symptomatic of a new era. And the distinctive mark of the new era is education of the people, not only education but enlistment as a fighting corps against preventable disease. Inspection, a pitiless publicity, freedom of discussion, recognition that mock modesty is intolerable—these are part of the new measures."*

The following statements sum up all of the arguments offered in this article and express in plain language results to be expected if society does not awaken to a full realization of its responsibility and pledge to eliminate race poisons from its midst.

Syphilis is declared by Osler to be the greatest destroyer of the human race.

At least eight to twelve per cent of all deaths are caused by syphilis. Most of such deaths are reported as heart disease, apoplexy, paralysis, locomotor ataxia, insanity, disease of the arteries, kidney diseases, or liver diseases.

The investigations of the most competent experts show that fully 10 per cent of the total population of this country are affected with syphilis, either active or latent.

Syphilis is directly heritable. It causes nearly one-half of all abortions, miscarriages, and stillbirths. Eighty per cent of the children of syphilitic parents die in early life.

Syphilis is the one racial poison, reducing the race standard by the breeding of mental delinquents, moral degenerates, and physically impaired. It is probably the greatest causative factor in inefficiency, insanity, pauperism, and crime. Thousands of persons, while supposing themselves cured, are harboring latent syphilis as a potent cause of degenerate progeny in the death of the victims themselves in middle life. In many cases death will be preceded by paralysis, insanity, or some chronic illness in which syphilis might not be suspected.

Insurance companies have found the death rate among people supposedly cured of syphilis to be double the rate of those who never had it.

Fully 25 per cent of the inmates of institutions for the insane and feeble-minded show active syphilis, and many more are there because of syphilitic ancestry.

Gonorrhea is the most common of all diseases except measles, and by far the most common, counting only cases which are at present infected.

Gonorrhea is responsible for 80 per cent of blindness of the newborn and for 25 per cent of all blindness.

Gonorrhea is directly responsible for about 75 per cent of the appallingly great number of abdominal operations on women, and for a large percentage of all so-called female troubles. The woman is usually an innocent victim of her husband's earlier indiscretions. Men should *know* they are cured—not just *think* so. In men gonorrhea causes sterility, rheumatism, heart disease, bladder trouble, stricture, prostatic trouble, and other complications.

Syphilis and gonorrhea cause more suffering and death than small-pox, diphtheria, infantile paralysis, and tuberculosis combined.

Where the Menace May Be Feared

In every city in the United States the "masher" or "male flirt" is to be seen on nearly every prominent street ogling women. This "street cootie," or "jelly bean," as he is called in certain sections of the country, is a barnacle on society and should be scraped off as being of no value to civilization. He attempts flirtations because of his lack of respect for women. He views every woman as being a purveyor of sensuality and as his prospective prey. He is at all times ready to pounce on innocence and to take advantage of its ignorance in order to accomplish his vile ends.

Many assert that flirting is an innocent pastime. It

*Louisville, Ky., Herald.

is, if the usual result of flirting—seduction—is considered proper. The average "masher," "street cootie," or "jelly bean" is more anxious to attack the virtuous girl or woman than he is to seek the company of those who sell their bodies for money. If parents would realize this and would warn their daughters, there would be fewer "brands to be plucked from the burning." If philanthropists and good men and women would understand this, hundreds of girls who from economic reasons have no parlors wherein they may entertain their sweethearts and must use street corners to meet men would be saved the degredation of being forced into prostitution, which in nearly every instance follows seduction.

Many times a girl in a spirit of fun will return a look or smile from a "masher" who may approach her, without realizing her danger. Too frequently these flirtations ripen into what may be mistaken for friendship, or even love, before she finds out the character of her supposed admirer too late to save herself from being burned by the scorching flames of sensuality and misplaced confidence.

Men who seek to take advantage of girls or women are usually diseased with either gonorrhea or syphilis, or both, contracted in the sowing of their wild oats. These individuals become a most prolific source for the spread of venereal diseases. They infect, during the first sexual embrace, women into whose ears they whisper words of love and promises of marriage. These misguided females, when they discover that they have become the victims of misplaced confidence through their ignorance of the wiles of their seducers and then learn that society's hand, to its shame, is turned against them, become social avengers. Thousands of women who are selling their bodies are getting a type of revenge on the institution that sent them into the "dark corners" that is sapping at the very vitals of civilization itself. The vendetta carried on by them is destroying its millions. They feed the flames of lust and burn with the fires of disease, bodies that might otherwise have remained pure and clean.

Because of its failure fully to appreciate the necessity for destruction of the causes for racial decay, society has been for centuries paying the penalty, and the penalty will become heavier each year unless vigorous methods are adopted whereby lust may be torn out by the roots. This can be accomplished only through a single standard of morality and through educational methods that will show the necessity for insisting upon continence in young men until marriage occurs.

Results of this nature cannot be accomplished by conspicuous reformers or by the sexually frigid. Only those who know what it means to fight a dominating sex appetite can ever expect to make themselves felt in a fight for a vigorous and strong race possessing inherent capacities for breeding strong children upon whose shoulders will fall the mantle of their parents to "carry on" after they are dead.

A vigorous campaign for the breaking up of loafing places wherein young men congregate should be started. The loafer, like venereal disease, is a "social menace." He is usually a teller of "dirty stories" to young men and an aid in starting them on the road downward. It is from his lips that the innocent first hear the polluted story of reproduction and first learn to regard girls and young women as being creatures put on earth for the sensual and sexual gratification of males. The pool room is the greatest harbinger of sex crimes to be found in any city. Instead of reformers attacking the "tobacco evil," which is more or less of an innocent pastime, they should busy themselves with things which involve civic welfare, certainly the pool room is a civic menace and as far as possible should be done away with.

The civic conscience should force the enactment of laws that would absolutely forbid the gathering together of small or large groups on sidewalks of the main thoroughfares of cities. Unless a man or group of men is able to give valid reasons for stopping on the streets, they should be forced to move on by the police. New Orleans has such a law, which has worked admirably for years.

The masher should be arrested. His punishment should be imprisonment, rather than a fine; in fact, a law that would refuse him bail and allow the judge no recourse to other than a sentence of imprisonment would go a long way towards his elimination. *Radical* measures are the only ones to be depended upon to clean up cities wherein are to be found causes for degeneracy.

One of the chief reasons for the non-enforcement of laws that will regulate loafing, mashing, etc., is civic apathy and hypocrisy, too many citizens maintaining that sexual indulgence is necessary for the physical welfare of young men before marriage. Another type of hypocrisy is mock modesty, which already has been briefly discussed.

Every citizen, whether he be business man, lawyer, doctor, politician, preacher, or policeman, should be made to realize that the "wild oats sower" or "masher" is desirous of attacking the virginity of the daughter he loves so well. It is an obligation he owes himself to protect his home. By safeguarding it he is doing his bit towards protecting the city in which he lives. He should see that laws that will guarantee safety to his virginal daughters are enforced.

The popularity of the automobile has made many sex crimes possible. Many an unprotected girl has been assaulted or persuaded to sacrifice her virginity by dissolute scions of homes wherein there is means sufficient to purchase automobiles for them. The lure of a "joy ride" has caused the "downfall" of hundreds of girls.

Freedom Merges into License

Parents are not careful enough of the society their children keep, therefore making their ruin easier of accomplishment. With the existence of too great a freedom today between the sexes and by the exposure of too much of the female body through an immodesty of dress that is in vogue, temptations that should be condemned are thrown in the way of young men. It is hoped that some day women, to use a phrase made popular by long usage, will again "wear enough clothing to hide their nakedness."

What has become of the chaperone of old, who performed her duties so well? The author can remember when in his youth he went to call upon a young lady that he was constantly aware of the fact that in the next room or somewhere close by was a guardian whose sole interest was centered in seeing that the welfare of the young lady he was calling upon was safeguarded. The young man in those days suffered no feeling of restraint nor did the girl; they took it for granted that her presence was proper. This guardian of the drawing room or parlor became a student of the characters of the young men who called upon the girl under her charge, and more than once was innocence saved from an attack from sensualism by her ever watchful eye. A chaperone who was a diplomat and knew how to advise the young was always popular. Proper chaperonage of young couples is to be desired. Certainly, now that the world is so vitally interested in the salvation of the race, young women and their escorts should be provided with a proper guardianship that would protect them from themselves and in many

instances from a flaring up of sex passion which might be mistaken for love, and thus many a false step could be prevented which might mean the ruining of their future lives. No normal and healthy minded young man whose intentions were pure would ever object to having his actions with his sweetheart supervised; his very love would cause him to desire it.

If the press would give publicity to sex crimes and would constantly advocate editorially their punishment, a social revolution would develop which would make it impossible for the sex criminal to exist. The newspaper is possibly the greatest agency for the dissemination of knowledge. It wields the balance of power and can do more towards cleaning up agencies of evil that spread racial scourges abroad than can sermons, lectures or pamphlets; these agencies are a mere drop in the bucket compared to the broad and beneficent influence of the press.

The influence of the preacher and the lecturer must not be decried. Their field of operation is broad and they should take advantage of their every opportunity to spread the gospel of social science and of venereal disease prevention abroad.

Humanitarian sermons and lectures can do much to change society's attitude toward the double moral standard and to bring, through pitiless publicity, venereal diseases into the light of day, where they may be attacked and destroyed. The pamphlet is a valuable aid in any campaign; it becomes a permanent record to be kept and reread from time to time. Pamphleteering in the fight against social diseases has already resulted in great good being accomplished, as can be attested by the United States Public Health Service and by state boards of health, through which institutions millions of pamphlets have been circulated on the subject of venereal disease. The public has been very much interested in reading any literature on the subject of the prevention of gonorrhea and syphilis. This literature is distributed without cost, and requests for it come in by the thousands. The United States Public Health Service or any state board of health stands ready to supply individuals, societies, schools, universities, colleges, or churches with pamphlets that will enlighten, and fit them to spread the gospel of social hygiene.

There can be no excuse on the part of parents today for ignorance, and those who profess it are in danger of having harsh criticism heaped on them by those who are interested in the elimination of prurience, hypocrisy and mock modesty, and who are trying to raise social and ethical standards to a point where they may be pointed to with pride as being the outcome of education and war.

Wholesome Community Life Needed

Each city should have community houses located wherever large groups of people live. "Civic Centers" should take pride in seeing that they are kept up. These community houses should be fitted up as clubs with club rooms and also with special parlors for use by boys and girls, where a degree of privacy may be had by them in their love making. Games of all sorts, including ten-pin alleys, should be provided, and a man and a woman employed to teach men and women how to play. Weekly dances, where the modern dance would be taboo and where the waltz and two-step would come back into its own, should be held under the chaperonage of men and women who possess humanitarian spirits and a knowledge of the needs of young people. Picture shows and amateur theatricals might be put on every few nights in an auditorium which should be a part of every community house. The services of expert entertainers and lecturers could be obtained at a very small cost.

A gathering place for boys and girls who have never had such a thing before, that would guide their play and at the same time provide wholesome amusement and the spending of a few hours of leisure in social communion, would do much to minimize the committing of sex crimes. A community which shows an interest in the welfare of its people is one wherein there is usually less vice.

Every church or public building that is not constantly in use should provide a means wherein a miniature community house can be located. Religious denominations as a rule have done very little for the social betterment of the neighborhoods wherein their churches occupy the most valuable property.

A spirit of "We'll all pull together" in any movement will eventually accomplish wonders, and should be encouraged by those who are thinking most about the future welfare of the race.

No city should count itself complete without a Young Women's Christian Association building. The Young Women's Christian Association offers a haven of refuge for hundreds of girls who find it necessary to earn their own living. Under the careful supervision of the splendid type of women who manage these buildings, girls and older women are made to feel that their interests are being looked after. Also a type of chaperonage is provided that actually protects girls from the terrors of a form of espionage that is nearly always present in the average cheap boarding house from a type of male who is unable to control his sex appetite and considers the working girl his prey.

These boarding homes, this is really what they are, provide living quarters at very reasonable rates to women who work or who may be attending school, or to transients who are unaccompanied by men. Usually a very superior cafeteria is maintained in connection with these institutions where food is sold at a very low price. The author has been told that through the careful management of the women who administer the Young Women's Christian Association at Madison, Wis., the profits from their cafeteria, open to the public, have in the few years it has been running paid for their building. Here the Young Women's Christian Association provides a general parlor where social gatherings are held and where a type of wholesome friendships may develop among women that will last a lifetime. These institutions make for morality in any community and teach a broad humanitarianism to women that makes them better employees, and afterwards, when the right man comes along and claims them, better wives and mothers. It would be impossible to overestimate the value of a Young Women's Christian Association to a city.

Any movement which has behind it sound principles for the improvement of society and the elimination of vice should receive careful consideration from parents and those interested in seeing the young womanhood and young manhood of America rise above mediocrity should fight to reach the highest point attainable to civilization.

The mothers must force themselves into a breach that has become very wide because of lax ethical standards and fight as they have never fought before for the principles that involve the very heart of the world, principles which, if put into practice, will make oncoming generations clean.

Every mother carries in her body the seed of a potential hero or heroine. Because of mock modesty, prurience, or hypocrisy, are these potentialities to be ruined? Are the women willing to engage in a battle that women can win

if their hearts are put into the cause? Or would they rather have their sons and daughters grow up ignorant—not innocent—and let them learn from the gutter things which will forever taint them and render them, in part at least, unable to "carry on" toward perfection of our present civilization?

Men are but instruments put into the hands of women to hew out of the rocks of time a pattern that shall exist for eternity. Man is but a pigmy compared to woman. From the wonderful laboratory under her heart he was conceived. He drank deep of the very nectar of her existence. She taught him, after he was born, to love and to hope. She gave him the elements of education that made him great or made him small. Through her he received a conception of God that would last him throughout his life. He is nothing more than the hand on the dial of the clock of the universe. The power of woman is the controlling force that drives the hand forward. The hand indicates only that which the propelling force intends that it shall.

Women have lived long enough in the dark forest of ignorance resulting from the paternal form of civilization which has enslaved them. If they are capable of giving birth to heroes, they certainly must possess the power to make heroines of themselves.

The full emancipation of women is at hand. Unfortunately, at present their fate is in the hands of women who, in our humble opinion, are not great. As yet they are in parrot fashion aping the tactics of men in resorting to political clap-trappery that will not do them credit. After the big brained, noble mothers of the race, who are not biologic non-essentials but who have actually brought into existence new entities, fully grasp the meaning of freedom and what it means to be released from man-made serfdom, they will blaze a trail in which men will be glad to follow. They, through the true elements of womanliness, will win over the present day "suffragette."

Men and women in America must cease being "whited sepulchers" and must come out from under the cloud of pharisaism and demand that the divine principles of nature be freed from the taint of diseases that produce degeneracy and interfere with the perfecting of the human machine.

Pay heed to the command of the prophet of old: "Arise ye; do that work which will cause your names to be placed in the halls of the blessed." The work is yours. Vice, with its diseases which destroy the fabric of society, is challenging you to mortal combat. Will you not don, as did the Maid of Orleans, the armor of truth and pledge yourselves to fight Lust, that men shall sanctify your names for having brought light into a place where once it was dark? Keep as your motto: "Above all nations humanity shall excel."

Listen to this wail of a heart-broken mother:

Through long and shattering pain I gave you birth;
It would have been far easier to have died,
But you, my baby, drew me back to life
By love and joy and pride.

And when God called on me to lay aside
My dreams for you and give His Cause, my boy,
I sent you out to fight—perhaps to die—
With pride and love and joy.

You have not died—you have not even fought—
Today I suffer more than all the pains
Your being cost. My pride, my joy, are gone—
Nothing but loves remains.

For all the service that you might have given,
And all the honor that you might have won,
You squandered for a harlot's poisoned kiss—
My son, O God! my son! —*Amelia J. Burr.*

Those desiring information as to the location of venereal disease clinics may obtain it by communicating with their state Board of Health or with the Surgeon General of the United States Public Health Service, Washington, D. C. The state boards of health are prepared to supply literature bearing on the control of venereal diseases and on the problems of social hygiene. Literature may be obtained also from the United States Public Health Service, which is cooperating with state boards of health.

AMERICAN LAWS FAVOR LABOR

As a part of their Americanization propaganda, the following summary is issued by the Inter-Racial Council as to the various methods of securing justice for the worker in the United States:

Laws enacted during 1919 to protect the lives and health of labor, contribute largely to the constructive movement, supported by both employers and employees, to help solve industrial problems by applying legislative methods, not as a matter of sentiment, but of sound economics.

This is indicated by the adoption of workmen's compensation in four more states—Missouri, Tennessee, Alabama and North Dakota, the last named state enacting an advanced law which provides for administering the compensation insurance in an exclusive state fund.

More than thirty states amended their compensation laws, generally along the line of more liberal cash and medical benefits for injured workers, shorter waiting periods before the payments begin, and wider scope. Ten states raised their scale of compensation so that there are now twenty-two states which provide compensation for injured workers of 60 to 66⅔ per cent of their wages.

Women's hours were reduced in half a dozen states, including an eight hour law in Utah and a nine hour limit in Massachusetts, secured after a full half century's struggle. Minimum wage laws for women and children were enacted in two additional states, North Dakota and Texas, making fourteen now in force, in addition to the District of Columbia.

Labor laws fared well last year in the courts. The United States Supreme Court upheld the women's eight hour law and workmen's compensation law of Arizona. The Supreme Court of North Dakota upheld the new workmen's compensation law in that state, including the exclusive state insurance fund. A Federal judge in North Carolina ruled against the new national Child Labor Law in a cotton mill case, but a final decision has not yet been handed down by the United States Supreme Court.

LEAGUE TO FIGHT TYPHUS

The typhus epidemic in Poland presents one of the most serious problems now before the League of Nations. The Typhus Commission of the League has asked its members to contribute $8,000,000 for fighting the plague in Poland and for protecting the rest of the world from a spread of the infection.

The campaign against typhus is especially difficult, according to Norman White, M.D., typhoid commissioner of the League of Nations, because soap, fuel, and other essentials of cleanliness are unprocurable, or extremely difficult to obtain. At the same time, there is a constant stream of refugees crossing the Polish border, many of them infected with typhus contracted in Russia.

The danger which an uncontrolled epidemic of typhus in Poland presents to the rest of the world is shown by the fact that in 1848 three hundred thousand persons died of this disease in Ireland.

BOOKS OF THE MONTH

Comment on Current Medical and Health Literature and Announcements of New Books

PASTEUR—THE HISTORY OF A MIND. By Emile Duclaux, late member of the Institute of France, professor at the Sorbonne and director of the Pasteur Institute. Translated by Erwin F. Smith and Florence Hedges, pathologists of the United States Department of Agriculture.[1]

This is more than a history of a mind. It is a history of scientific achievement in many lines of endeavor which contracted the powerful force of Pasteur's personality. The book, although technical in many spots, is full of interest—interest in part divided between Pasteur and his biography. As a biography it deserves a place in every medical man's library. As a historical treatise on many scientific fields it has a similar value.

THE DIAGNOSIS AND TREATMENT OF HEART DISEASE. Practical Points for Students and Practitioners. By E. M. Brockbank, M. D. (Vict.), F. R. C. P., Hon. Physician, royal Infirmary, Manchester; lecturer in clinical medicine, dean of clinical instruction, University of Manchester.[2]

The fourth edition of this little book contains just as much as previous editions had contained. Like all small books of this kind it has a definite value, especially in the teaching field.

THE DUODENAL TUBE AND ITS POSSIBILITIES. By Max Einhorn, M. D., professor of medicine at the New York Postgraduate Medical School.[3]

Contemporary medical history is being made around the duodenal tube. To the author of this book belongs a great share of the credit for the introduction of the duodenal tube into medical practice, for the development of its use and the extension of its application. Einhorn has collected in this volume most of his papers and has put in a very attractive readable form modern knowledge and future possibilities of the duodenal tube. Incidentally, the book is beautifully gotten up. The illustrations are excellent, the typing and paper work unusually good.

EXOPHTHALMIC GOITER AND ITS NONSURGICAL TREATMENT. By Israel Bram, M. D., instructor in clinical medicine, Jefferson Medical College, Philadelphia, Pa.[4]

This book contains a very good review of the subject of exophthalmic goiter as studied from the literature as well as from the author's personal experience. In many instances it is regrettable that the book has appeared just at the time it did, as certain important contemporary subjects are not given the consideration warranted by the present day thought on them. For instance, in the discussion of the differential diagnosis between exophthalmic goiter, "shell-shock," or the irritable heart of soldiers, we miss reference to Peabody's excellent work on this subject. The work of basal metabolism received scant notice, although surely the work of Boothby, Rowntree, McCaskey, and others has shown that in basal metabolism we have a means of quantitative determination of the degree of thyroid disturbance as well as of the effects of treatment.

We also think that in a book of this sort greater effort should be made to standardize nomenclature. The type of disease presented agrees with the classifications of Plummer, but the use of different names is confusing.

The discussion of the nonsurgical treatment is full of excellent detail which any internist attempting to handle these patients will find of value.

YOUR HEART AND HOW TO TAKE CARE OF IT. By Robert H. Babcock, M. D., LL. D. Author of "Diseases of the Heart and Arterial System," etc.[5]

This volume of 235 pages gives concise instructions to the individual with heart disease on how to live in order to get the most service from his impaired organ. It explains the meaning of the various symptoms of broken compensation while showing the unimportance of the various manifestations which cause unnecessary anxiety to the hypochondriac. It instructs the man with arteriosclerosis how to modify his life in order to stay the process. Most important, the author not only shows how careless or too strenuous living causes damage to the vascular system but devotes a great deal of space to the effect of the various infections, especially the Streptococcus, on the heart. The importance of proper care during attacks of infections, whether tonsilitis, rheumatism, or a common "cold," in order to avoid damage to the heart, is dwelt upon at length.

THE NOSE, PARANASAL SINUSES, NASOLACRIMAL PASSAGEWAYS, AND OLFACTORY ORGAN IN MAN. A Genetic Developmental and Anatomico-Physiological Consideration. By J. Parsons Schaeffer, A.M., M.D., Ph.D.[6]

The importance of inflammatory processes of the nose and paranasal sinuses as an etiological factor in the production of morbid anatomy in closely associated structures, and more generally when classed as focal areas in more remote disease, is calling forth at the present time much study and thought. This book comes as a valuable aid to clear understanding of the development, status in childhood and in maturity of these structures, covering in its twelve chapters the embryology, anatomy, and physiology, an understanding necessary to an appreciation of variations from the typical, or from the normal, and to the carrying out of treatment and prognosis.

This valuable monograph makes it possible for the student to go far toward the mastery of the subject with this treatise alone.

A NURSE'S HANDBOOK OF OBSTETRICS. By Joseph Brown Cooke, M.D. Ninth Edition revised and enlarged by Carolyn E. Gray, R.N., University of Pennsylvania.[9]

A work appearing in its ninth edition does not call for a detailed description of its contents or specific features; it has definitely established its value and is known to all teachers of obstetrics. With every new edition the authors have added some new material to incorporate latest advances in knowledge, or to discuss newer problems of general interest, in this new edition such features cover chiefly the question of public nursing. This endeavor to keep the work abreast with recent progress in itself surely is most commendable, but inevitably it leads to a steady increase in the size of the volume, which is an undesirable and, indeed, objectionable feature, but one that could easily be obviated in the next edition by the elimination of some unnecessary matter, such as references to details of operations, pathologic conditions, etc. Overtraining of nurses, at least in part, is responsible for the present unsatisfactory nursing situation in this country. Books of this character tend to force on the pupil nurse much knowledge she does not require.

HOME NURSING. By Abbie Z. Marsh, Portland, Ore.[10]

In the belief of the author of this interesting little volume, hospitals will help, but hardly ever will entirely solve the problem of caring for illness. Home care, at least of those not very seriously sick, is a question calling at this time for most careful consideration. The writer of this book is of the opinion that the principles of home nursing could be successfully taught in the school in connection with domestic science and should be included in benefit of such more or less compulsory instruction would seem obvious.

Taking for granted an elementary knowledge of anatomy, physiology and hygiene, as already commonly taught, the author presents her own subject of home nursing in three distinct parts. Part I deals with the technic of nursing and takes up the larger part of the book. Presumably this subject could be covered in fifteen lessons of from one to two hours each. Part II presents the symptoms of and simple methods of dealing with the common diseases. The volume ends with Part III, discussing the care and feeding of infants. Parts II and III would not necessarily be included in the public school course, but cannot fail to prove of great value as reference and safe guide in the student's future needs.

The book is written in simple language, is well illustrated, and serves a purpose worthy of most serious consideration under present economic conditions.

THE SOCIAL PROBLEM. A Reconstructive Analysis. By Charles A. Ellwood, Ph.D., professor of sociology in the University of Missouri. Author of "Introduction to Social Psychology," "Sociology and Modern Social Problems," etc.[11]

Nothing new is added in this contribution by Ellwood to his former contributions on social psychology, but according to principles previously enunciated, he makes a highly interesting analysis of the psychologic causes underlying existing social disorganization.

Civilization, he says, is at bottom of the creation and transmission of social values by which men regulate their conduct and the immediate roots of civilization are always in the mental values of individuals. He sees dehumanizing conditions in industrialism and disintegration as the result of materialistic ideals of life. The real cause of the Great World War is to be found in our predatory tradition, the doctrine of the spoliation of one's competitors as the surest means of advancing one's self, and the same forces, still operative, make for the present disorganization.

The remedy is to be found in a synthetic view of social life. He warns against one-sided views and remedies. Effective control must be attained by the control of all factors of importance—heredity, environment, economics, and, most of all, the development of individual character through education. We live together by the mutual exchange of services, goods, and sacrifices and the theory of spoilation is a delusion.

No static solution of the social problem is possible. The recognition of the solidarity of the interests of classes, nations, and races will make for that plasticity of personal opinion, and of institution which provides for growth and new adaptations.

He holds that "Social Progress does not come automatically, that it must be intermediated by thought and effort; that a process of social reconstruction, if it is to endure, must be an educational process; and that education is therefore all important in social reconstruction. We shall build the superior society of the future just as we produce the superior engine—by scientifically trained minds that know social facts and forces so that they can map out and plan a superior social organization which in turn shall produce individuals of superior intelligence and character."

THE CONTROL OF HUNGER IN HEALTH AND DISEASE. By Anton Julius Carlson, Professor of Physiology in the University of Chicago.[12]

The Control of Hunger in Health and Disease is a report by Anton Julius Carlson of work done in the University of Chicago. This study of the stomach was made with special reference to appetite and hunger and was carried through a period of four years. Methods for studying the tonus and contractions of the empty stomach are given as (1) direct inspection, by means of a gastric fistula, (2) the introduction of a rubber balloon into the stomach, either through the esophagus or the gastric fistula; (3) the introduction into the stomach of a balloon coated with bismuth paste on the inside. These three methods were all used by Professor Carlson and details of procedure are given including specific directions for work as well as the results, and observations in each case.

A chapter on the Relation of Hunger to Appetite points out the fallacy of the opinion commonly held, particularly by the laity, that hunger and appetite are sensations of the same quality, differing only in intensity. This view is no longer accepted by those who have given attention to the subject. Professor Carlson emphasizes the need for further investigations and urges that more intensive work in this field be done by the medical man and biologist.

Since it is a well recognized fact that control of hunger and appetite influence greatly the control of disease, particularly of chronic disorders, the continuance of this study would be a valuable contribution to science. We look for the cooperation of the physiologist and the clinician as the logical ones to carry these investigations further. In reading this summary, one is impressed with the fact that the work was very carefully done, therefore, a good foundation is already laid for this research work. As it stands it affords the best and most accurate record available of work in this important field.

CUNNINGHAM'S MANUAL OF PRACTICAL ANATOMY. Revised and edited by Arthur Robinson, professor of anatomy in the University of Edinburgh. Volume I, Superior Extremity, Inferior Extremity.[13]

With the seventh edition of Cunningham's Manual of Practical Anatomy a triplet of little green books will take the place of the well known twins. New descriptive matter and many new cuts have been added and, in order to maintain the present size of the books, their number was increased.

The addition of the x-ray photographs is a great improvement. Judging from Volume I (the only volume which as yet has reached the reviewer) normal anatomy from a radiographic point of view will be well covered. The idea of demonstrating the relation of the blood vessels to the bones by means of roentgenograms of injected specimens is an excellent one.

Another point which should receive favorable comment is the retention of the B.N.A. nomenclature along with the old terminology. During the war there was a tendency among English and American writers to give up the B.N.A. names. We are glad to see that Dr. Arthur Robinson, the editor of the seventh edition, has not been influenced by this tendency, but still believes that a single nomenclature universally adopted by scientific men is preferable to the present confusion.

DIE EXPERIMENTELLE BAKTERIOLOGIE INFEKTIONSKRANKHEITEN Besonderer Berucksichtigung der Immunitatslehre. Ein Lehrbuch for Studierende Arzte und Medizinalbeamte von Dr. W. Kolle, Direktor des Institutes für experimentelle Therapie, o. Honorarprofessor an der Universitat Frankfurt a. Main, und Dr. H. Hetsch, Prof., Privatdozent, Oberstabsarzt, im sanitatsdepartement des Kreigsministeriums in Berlin.[14]

The popularity of Kolle and Hetsch is very clearly indicated by the rapid appearance of the fifth edition of this brilliant work and its translation into French, Spanish, Italian and Russian, shows in a somewhat universal manner the thoroughness of which its subject is covered and is perhaps the best index of the text's usefulness and the enthusiasm with which it has been received.

The volumes are quite up to date reporting practically all of the work that has been done in Europe since 1914 and gives clearly much of the work that was closed to the allied countries during the war, for this reason it is quite valuable and well deserving to be brought to the attention of the workers in bacteriology and infectious diseases.

Volume one shows an increase of 150 pages and several new chapters over the previous edition. Each chapter, with two exceptions, has been entirely rewritten, additions having been made to the extent that the text is undoubtedly the most modern published in any language. Practically all of the late work done in intestinal diseases—typhoid, cholera, and dysentery,—cerebrospinal meningitis, streptococci, gas bacillus, and pneumococcic infections will be found in their respective chapters. A chapter devoted to botulism has been added which gives very clearly and accurately a splendid description of the organism and its clinical and pathological manifestations. Of particular interest is the chapter on influenza, giving all the data that the German workers obtained during the epidemic of 1918-1919. It can be properly said that this is the most thorough description that has yet appeared in any of the texts relating to bacteriology and infectious diseases.

Volume II has been quite markedly changed. New chapters on Weil's disease, Vincents' angina, chemotherapy, Leishmania, filterable virus, Dengue and Pappataci fever, poliomyelitis, trachoma, verruca peruana and infectious filterable viruses for animals. Typhus fever, Werner-Hiss disease, and bilharziasis, have been added. These additions have materially enhanced the value of the text and serve to make it as complete as any publication of this nature.

The chapter on chemotherapy deserves special mention for it includes a description of the work of Wassermann on the action of selenium compounds in mouse carcinoma, silver salvarsan, and other salvarsan preparations, and a general review of chemotherapy from Ehrlich's first work up to the present, touching the various phases that have been developed along lines other than those of the arsenical preparations.

This work has been arranged in a more logical manner than the previous editions, and the chapters so grouped that they are more relevant. Many diseases will be found carefully and thoroughly described here that are barely every girl's education. The far reaching and general mentioned in the average text. It is more than a textbook, at least in its completeness one can readily see its value as a reference book. Yet it can be recommended to the beginner, especially to those interested in the bacteriology of the infectious diseases, for even the fundamental principles of the general bacteriological methods English translation has not yet been published so that have not been slighted. It is a regrettable fact that an such a useful text might be available to all English speaking bacteriologists.

ARTERIOSCLEROSIS AND HYPERTENSION With Chapters on Blood Pressure. By Louis M. Warfield, A.B., M.D. (Johns Hopkins), F.A.C.P.[15]

Arteriosclerosis is only a symptom, but it is an important symptom or, rather, sign. It tells of the strain of our life, of the difficulties that befall us, of the burden on our heart and blood vessels. It is highly important that some one should interpret the sign, should discuss the whys and wherefores, and should suggest some means of combating it. This task Warfield has undertaken, and he has carried it out quite successfully. He discusses arteriosclerosis from every angle and makes some fine suggestions. The book has gone through three editions.

THE OPERATIVE STORY OF GOITER. The Johns Hopkins Hospital Reports, XIX, Fasciculus II. By Dr. William S. Halsted, Baltimore, Md.[16]

The author has made a most painstaking study of the literature on goiter, relating to early operations. He has studied many cases of reported early excisions of the thyroid and shows that they are not authentic. The undoubted confusion in the minds of early surgeons between actual goiter and diseased lymph glands, he proves. To establish this proof he quotes statements from G. B. Günter's famous work and from many other reliable source, as follows:

According to Schreger, Celsus had already undertaken the extirpation of goiter. But it is clear from the text that in the chapter which Celsus entitles "De Struma" lib. vii, 13, the author, in the use of this term, has not in mind a disease of the thyroid gland, but rather a swelling of the lymph glands. Of goiter proper he speaks in lib. vii, cap. 13, under the title "De Cervicis Vitio." Here he describes, unmistakably, cystic goiter, and says, after discussing the use of caustics, *"sed scalpelli curatio brevior est."*

According to Mandt in Rust's Magazin, xxxvii, 413; and Langbeck, Chirurgie, v, 306 (note), Albucasis is listed among those who performed this operation about the year 330. In the local library I have not been able to find any passages bearing on this.

PUBLIC HEALTH and HYGIENE

By Eminent Authorities

Edited by WILLIAM HALLOCK PARK, M.D.

PROFESSOR OF BACTERIOLOGY AND HYGIENE, UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE; DIRECTOR OF THE BUREAU OF LABORATORIES, DEPARTMENT OF HEALTH, NEW YORK CITY

Octavo, 884 pages with 123 illustrations. Cloth $10.00 net

A remarkable advance has taken place, in the past few years, in the appreciation of the people and of their officials in regard to the value of public health. This growing opinion that public health is to a large extent purchasable by effort and money, has stimulated health authorities to develop their opportunities and to assume greater responsibilities. The best medical colleges no longer confine their teaching almost wholly to subjects dealing with the diagnosis and treatment of disease, but give thorough courses in hygiene, and its practical application in preventive medicine. The technological schools are providing similar courses to students thinking of entering the field of public health work.

The great advances in our knowledge concerning hygiene and the increasing scope of public health work have led to the creation of many subdivisions and the problems and practices connected with these have become so highly technical as to require public health workers to restrict their activities to special lines. The medical officer for some time has appreciated this. Wherever the community is large enough to afford it, he has obtained the service of specialists to administer and develop the different departments. The department of health of any progressive State or large city has under the administrative head a number of bureaus, each of these under some specialist who has demonstrated his fitness.

The time has passed when any one person can possess the technical knowledge and personal experience required properly to direct and develop all or even several of these different branches of public health work. It is also true that few if any persons can discuss authoritatively more than one or two of these subjects. The report of the American Public Health Association on the control of communicable diseases was consulted in writing the chapter on that subject.

The writers of this book, holding the above opinions, believed that there was need of a volume in which the most important phases of hygiene in relation to public health would be presented in a practical way by specialists actually devoting themselves to the subjects treated by them. The writers have kept in mind that the book is intended for public health officials, physicians and medical students, and each has therefore tried to make his section as practical as possible and to utilize to the full his own personal experience.

CONTENTS

Relation of Microorganisms to Disease
WILLIAM H. PARK, M.D.

Antimicrobal or Antiprotein Substances Individually Considered
WILLIAM H. PARK, M.D., AND CHARLES KRUMWIEDE, M.D. Assistant Director of the Bureau of Laboratories; Associate Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, New York City.

Prevention of Individual Infectious Diseases
WILLIAM H. PARK, M.D.

Practical Use of Disinfectants
WILLIAM H. PARK, M.D.

Epidemiology
GEORGE A. SOPER, PH.D. Major, Sanitary Corps, U. S. A.

Sanitary Surveys
W. L. DODD. Assistant Director of the Department of Sanitation of the Pease Laboratories, New York City; sometime Sanitarian-in-Charge of the Metropolitan Life Insurance Co., New Orleans Sanitary Survey.

Air and Health—Ventilation
C.-E. A. WINSLOW, DR., P.H. Professor of Public Health, Yale School of Medicine; Curator of Public Health, American Museum of Natural History, New York.

Housing
LAWRENCE VEILLER. Secretary of the National Housing Association, New York City.

Food
EDWARD K. DUNHAM, M.D. Lieut.-Colonel, Medical Corps, U. S. A.

Vitamines
ALFRED F. HESS, M.D. Clinical Professor of Pediatrics, New York University and Bellevue Hospital Medical College, New York City.

The Preservation and Adulteration of Food
J. P. ATKINSON, M.S. Chief Chemist, Department of Health; formerly Research Chemist to the Bureau of Laboratories, City of New York.

Bacterial and Other Contaminations of Milk. Their Relation to Public Health
WILLIAM H. PARK, M.D.

Bacterial Infections and Parasitic Diseases from Milk, Meat and Other Foods
WILLIAM H. PARK, M.D.

The Soil
ARTHUR R. GUERARD, M.D. Lecturer on Social Hygiene, New York State Department of Health, New York City.

Water Supplies and Their Purification
JAMES T-B. BOWLES, B.S. Lecturer in Water Supply and Sewage Disposal, New York University, Department of Hygiene, Bellevue Hospital Medical College; in charge of Water Supplies and Purification Plants, Canal Zone, Panama; Sanitary Expert with Expeditionary Forces; Vera Cruz, Mexico; Formerly Lieut.-Col., Sanitary Corps, U. S. Army.

Sewage and Waste Disposal
JAMES T-B. BOWLES, B.S.

Housing and Plumbing
ARTHUR R. GUERARD, M.D.

The Sanitation of Swimming Pools
WALLACE A. MANHEIMER, PH.D. Chairman of the Department of Physical Training, Evander Child's High School; Vice-President of the International Congress on Public Baths, Belgium, 1920.

Personal Hygiene
EUGENE LYMAN FISK, M.D. Medical Director of the Life Extension Institute, New York.

Additional Practical Points in Personal Hygiene
ARTHUR R. GUERARD, M.D.

Military Hygiene
C. W. BERRY, M.D. Lecturer on Military Hygiene, New York University and Bellevue Hospital Medical College; Lecturer on Preventive Medicine, Long Island Medical College, and the Post-Graduate School, New York City; Brigadier-General, New York National Guard; Adjutant-General of the State of New York.

Rural Public Health Work
FRANK OVERTON, M.D., P.H., SC.C. Sanitary Supervisor, New York State Department of Health.

Tropical Hygiene
M. E. CONNOR, M.D. Health Officer, Panama Canal, 1904-1914; Superintendent of the Medical Department, United Fruit Co., Tela, Honduras, 1914-1916; Senior State Director, International Health Board.

Industrial Hygiene
LOUIS I. HARRIS, M.D. Director of Bureau of Preventable Diseases, City of New York; Special Lecturer, Department of Bacteriology and Hygiene, New York University and Bellevue Hospital Medical College; Medical Advisor to the Labor Sanitation Conference, Greater New York.

Child Hygiene
S. JOSEPHINE BAKER, M.D., D.P.H. Director of Bureau of Child Hygiene, Department of Health New York City; Lecturer on Child Hygiene at Teachers' College, Columbia University and New York University and Bellevue Hospital Medical College; Consultant in Child Hygiene, U. S. Public Health Service; Former President of the American Child Hygiene Association.

Sociologic and Economic Aspects of Disease
CHARLES F. BOLDUAN, M.D. Lecturer on Preventive Medicine and Hygiene, College of Physicians and Surgeons (Columbia University), New York; Chief of the Section of Public Health Education, U. S. Public Health Service, Washington, D. C.

Public Health Education
CHARLES F. BOLDUAN, M.D.

Mental Hygiene
AUGUST HOCH, M.D. Late Director, Psychiatric Institute, Manhattan State Hospital for the Insane; late Chief Psychopathologist, Cornell Dispensary, New York.

Mental Defectives. Preventing and Controlling Measures
HENRY H. GODDARD, PH.D. Director of Bureau of Juvenile Research, Columbus, Ohio; formerly Director of the Psychological Laboratory, Vineland Training School, Vineland, N. J.

Maritime Quarantine
LELAND E. COFER, M.D. Surgeon, U. S. Public Health Service; Health Officer of the Port of New York; Member of the Board of Health, N. Y.

Vital Statistics
WILLIAM H. GUILFOY, M.D., Registrar of Records, Department of Health, New York, and SHIRLEY W. WYNNE, M.D. Chief of Division of Statistical Research Department of Health, New York; Member of the Advisory Committee on Statistics, New York Tuberculosis Association.

SUBSCRIPTION

Domestic postage, $3.00. Foreign postage, $3.50 (15 shillings). Single copies (regular), 25 cents.

Domestic rates include United States, Cuba, Mexico, Porto Rico, Canal Zone, Hawaii, and Philippines.

SUBSCRIPTIONS.—Subscriptions may begin at any time. Volumes begin January except in the case of Volume I, which consists of the numbers issued during 1919 (May to December, inclusive).

REMITTANCES.—Remittances for subscriptions should be made by check, draft, post office or express money order, or registered letter. Make all checks and money orders payable to MODERN MEDICINE.

CHANGE OF ADDRESS.—Notice of change of subscriber's address should give both old and new addresses. Notice should reach us fifteen days in advance of date of publication.

COMMUNICATIONS.—When communications relate to more than one subject (manuscript, reprints, subscriptions, news items, etc.), correspondents will confer a favor by writing on a separate sheet for each subject, thereby insuring more prompt attention.

ADVERTISEMENTS.—The advertising pages of MODERN MEDICINE are available for announcements of anything of interest and service to those engaged in the treatment and care of the sick and especially to those who are devoting their efforts to organized medical and health work. Advertisements of secret remedies and other objectionable announcements will not be accepted. The supervision of the Editors is extended to the advertising columns, in which only approved products and reliable manufacturers will be represented.

CLOSING OF FORMS.—Advertising forms close on the 10th for the issue of the following month. Ample time should be allowed for composition of advertisements and the sending and return of proofs.

ADVERTISING RATES.—Advertising rates will be sent on request.

CONTRIBUTIONS.—Original articles on any problems of practical interest to our readers are respectfully solicited from those who can write authoritatively on current problems in social medicine, hygiene and medical service in industry, public health and allied subjects. Articles are accepted for publication with the understanding that they are contributed solely to MODERN MEDICINE.

ILLUSTRATIONS.—Such half-tones and zinc etchings as in the judgment of the Editors are necessary to illustrate articles will be furnished when photographs, drawings, or ink tracings are supplied by the author.

NEWS MATTER.—Our readers are requested to send in items of news, and also marked copies of newspapers containing matters of interest. We shall be glad to know the name of the sender in every instance.

BOOKS OF THE MONTH

(Continued from page 838)

SURGICAL SHOCK AND THE SHOCKLESS OPERATION THROUGH ANOCI-ASSOCIATION. By George W. Crile, M.D., and William E. Lower, M.D. Edited by Amy F. Rowland, B.S.[7]

Crile and Lower discuss shock, its causes and its preventions. They view the subject in the light of their theory of the kinetic drive and do not attempt to give any other views. The main principles of their theory of shock are well known to all who have kept abreast of the modern surgical writings. Shock is the result of a series of afferent nerve impulses which bring about changes in the brain cells and also in other tissues, identical with the changes brought about by exhaustion. The prevention of shock lies in the blocking of these nerve impulses in the afferent limb of the nerve arc.

The first part of the book is devoted to a careful, detailed study of their theory—giving results of numerous laboratory and clinical experiments. On these results a new principle of operative surgery has been founded. Every adequate stimulus, whether from trauma or emotion, predisposes to shock by causing cellular changes in the brain. The inhalation anesthetic excludes psychic stimulation but does not exclude the operative stimuli. The operative stimuli are excluded by careful, gentle manipulations and by blocking the afferent nerve impulses by infiltrating with novocain. The latter two-thirds of the book is devoted to the technic of anociation.

The book is very readable, clear and well illustrated. There are innumerable helpful suggestions as regards pre-operative and postoperative care of the patient, technic of local anesthesia, etc., which will well repay the surgeon for his careful perusal of the work, whether or not he believes in the kinetic drive or holds to any other of the numerous theories of the cause of shock.

INFECTIOUS DISEASES. A Practical Textbook. By Claude Buchanan Ker, M.D., Ed., F.R.C.P., Ed., medical superintendent, City Hospital, Edinburgh, and lecturer on infectious diseases to the University of Edinburgh, etc.[8]

This is the second edition, intended for publication in 1914, but delayed until this year because of the Great War. It is a practical textbook based in the main on the author's personal experience with a very large series of cases. Although its language is not concise, the book is interestingly written, well indexed and has excellent plates.

The signs and symptoms, differential diagnosis, complications and treatment are well handled, but unfortunately the author gives too little attention to the bacteriological phases of infectious diseases. No reference is made to the results of research of the last few years which has defined many of the variables that are factors in the virulence of infections and has demonstrated the serum bactericidal reactions which are the body's last defense against attack.

The last chapter is devoted to the "fever hospital problems" of today, in which the author shows an authoritative knowledge of the situation. There are several contradictory statements in the chapter on measles and too much attention was given to Duke's disease. The book, unfortunately, has the fault of not containing a complete bibliography. This is a serious omission and robs all texts of considerable value as reference books.

On the whole, this book of Ker's can be recommended as an excellent textbook on infectious diseases.

What Cooks Don't Know About Food Preparation Increases The Mortality Rate

EVERY physician knows that the best medical care, the most scrupulous attention to regimen can be discredited and undone by a course of badly-prepared food—or even by a few meals of improperly-prepared food. Indigestible, or badly-assimilated food, may be the predisposing, if not the exciting cause, of many ailments medical men are commonly called upon to treat.

Butter, goose-grease, lard, and ordinary cooking compounds, which burn at a low temperature, are absorbed into the cell structure of the food—coating over the particles, rendering them infinitely less digestible.

Also, the low burning point of ordinary cooking fats tends to develop acrolein — intensely irritating to the delicate mucosa of the stomach and intestines.

Mazola can be heated to upwards of 650° before burning. The intense heat possible with Mazola cooking sears over the surfaces of the meat, fish, or other food; keeps in the savory juices and meat extracts, and prevents the absorption of the fat used in cooking. This, naturally, increases the digestibility and assimilability of the food.

Mazola is also perfectly delicious, used as a salad oil—replacing olive oil. Mazola carries from one to one and one-half per cent of lecithin—giving it thereby this additional advantage in all nerve exhaustion and wasting conditions.

Advise your patients to use Mazola, Doctor, for all cooking and salad purposes, and help them overcome under-oxydation conditions.

SERBIAN RELIEF FUND

The annual report of the Serbian Relief Fund just issued affords proof of what American energy, combined with scientific classification, can do in reaching the men deserving of health and those most likely to be permanently benefited by it. Serbian relief has included agricultural relief, the typhus mission, baby hospitals, dispensary ambulances, hospital supplies, clothing for civilian refugees, scholarships for needy students, and regular monthly stipends for young children and for destitute aged women. More than three thousand cases of distress were relieved during the past year, of which number 2,500 are receiving regular allowances. Hundreds of young men and women who are now self-supporting owe their education and health to the Serbian Aid Fund.

MASSACHUSETTS HEALTH COUNCIL

There has been organized recently in Massachusetts by the state-wide health agencies, a Massachusetts Central Health Council, for the purpose of promoting cooperation between the various health activities throughout the State. It is expected that by means of this organization duplication and overlapping of duties may be eliminated and that the financial and legislative needs of health agencies may be supported with increased efficiency.

The initial activities of the Massachusetts Central Health Council will be of an advisory nature. One of the first steps to be taken will be the outlining of the programs and problems of each of the constituent organizations, thus making it clear to each organization what the others are doing and propose to do. It is hoped also that cooperation and counsel may help to clarify the present confusion in regard to the respective duties of health officers and volunteer agencies.

In the new organization are represented public health nursing, child welfare, medical and dental groups, tuberculosis, cancer, state and local health officials, the American Red Cross, and the American Public Health Association. Dr. Enos H. Bigelow, Framingham, is president of the Council; Mr. Arthur G. Rotch, American Red Cross, Boston, vice president; and Mr. A. W. Hedrich, American Public Health Association, Boston, secretary-treasurer.

MICHIGAN CONTROLS DISEASE CARRIERS

Steps are now being taken in Michigan toward the control of communicable disease carriers under a regulation of the Advisory Council of Health.

"Any carriers," reads the regulation now being distributed to physicians and health officers throughout Michigan, "of a dangerous communicable disease that under the rules and regulations of the Michigan Department of Health is subject to quarantine or isolation shall be isolated or quarantined as provided in said rules and regulations, and shall not be permitted to attend any school, church, theater, or other public assemblage, or otherwise come in contact with the public." The term "carrier" is interpreted to apply to any person harboring the virulent organisms of a communicable disease. Though the carrier may not be sick himself, he may spread the virulent organism and cause severe epidemics.

The examination of three hundred school children in one village resulted in the detection of eight diphtheria carriers. The results to be achieved by the pre-school examinations of school children to discover disease carriers is well worth the money cost and effort, according to William J. V. Deacon, M.D., who is the director of the Bureau of Communicable Diseases.

Sleep Restores the Balance of Efficiency

Loss of sleep is a form of starvation more certainly destructive, even, than that resulting from the lack of food.

Sleep, on the other hand, reserves the downward trend caused by our waking activities and elevates us, physically and mentally, to a point of efficiency commensurate with the quality and quantity of sleep we have experienced.

A scientifically built mattress is not the least important factor in inviting sleep of complete relaxation and thus completely restoring the balance of efficiency.

In the Sealy Mattress every requirement of hygienic design, sanitary construction and physiologically correct service has been met. Only antiseptically cleaned long fibre cotton is used and the special air-weave process makes it a complete unit *without tufting.* This mattress invites deep, restful sleep because of its resiliency, and because of the unbroken, smooth surface which molds itself to support every part of the body.

The Palatability of Food
Depends on

Flavor

Flavor stimulates a desire for food to which it is added, and helps the convalescent to take the proper nourishment necessary.

Tempting flavors are important in convalescence when every day's diet counts for rapid recovery and where it is so hard to provide nourishing and wholesome foods that are likewise palatable to the invalid.

SAUER'S
THE NATIONAL EXTRACT
VANILLA AND 32 OTHER FLAVORS

They are made from the choicest materials obtainable in a modern and sanitary plant where every care is taken in their manufacture.

Sauer's Extracts have won seventeen highest awards and medals at American and European Expositions for purity, strength and fine flavor.

The C. F. Sauer Company

Richmond, Virginia

ANALYSIS OF CASE REPORTS

The campaign against venereal disease will be more effectual when better analysis brings out the meaning of certain fundamental facts. By such means we could understand better in what economical groups venereal diseases constitute the greatest menace, at what ages their incidence and prevalence are highest, with what social conditions their prevalence is most directly associated, and what agencies can be used to the greatest advantage in preventive work. An article by C. C. Pierce, assistant Surgeon General, recently published in *Public Health Reports*, argues that venereal disease infections tend to occur most frequently among that class of population which leaves school before education along these lines has been given, and effective means must be devised to carry education where it will do most good.

SURVEY DISEASED TONSILS

The Health Department of the City of Rochester, N. Y., has made a survey of the condition of children's tonsils and the newspaper reports indicate that a startling condition, affecting not only the present health of the children of Rochester but their future well being, and constituting a serious menace to the whole community, has been revealed. The astounding conclusions reached as a result of the investigation are summarized as follows:

That apparently 27,748 children attending the public schools of Rochester have enlarged and diseased tonsils and adenoids and should be operated upon if they are to develop physically and mentally as they should.

That 18,498 of these children presumably belong to families of limited means who cannot afford to pay the fee charged by the regular practitioner for the tonsil-adenoid operations, and must be taken care of at clinics.

That 9,249 of these children belong to well-to-do families, able to pay the regular practitioner, and should be taken care of in regular practice.

The survey reported was a direct result of the recent intensive tonsil-adenoid clinic conducted by the Rochester Dental Dispensary, at which 1,470 children were operated upon during a period of seven weeks. The large number of children appearing for examination at that time and the fact that 2,256 operable cases were listed which could not be given the benefit of the operation, led Dr. George W. Goler, city health officer, to conduct a survey in the schools with a view to determining the number of children in Rochester actually afflicted with the disease-breeding growths.

The throats of 3,187 children attending School No. 20, School No. 23 and School No. 27 were examined by two physicians, one representing the Health Bureau and the other the Rochester Dental Dispensary, both agreeing in the diagnosis made.

These examinations revealed the following facts:

That 2,792 children, or 87 per cent, needed operation for enlarged and diseased tonsils and adenoids.

That of the 2,792 children thus afflicted, only 856, or 26 per cent, had been previously operated, and that 1,936, or 61 per cent, still require the operation.

That in the case of 776 children, or 24 per cent, immediate operation is not urgent; in the case of 762, or 24 per cent, operation is urgent, and in the case of 598, or 19 per cent, operation is very urgent. In all these cases operation not only is desirable, but imperative, from the standpoint of the best physical and mental development of the child. Rochester is the one city which has provided complete service of this character in the interests of preventive medicine and developments are awaited with interest.

HEBE

the new food product reclaims wholesome skimmed milk for human food.

SKIMMED MILK—millions of pounds of it containing the body-building, strength-giving elements so necessary in our diet are wasted annually. And this because lacking a fat content skimmed milk does not appeal to the palate as a beverage, nor does it find acceptance generally as a cooking medium.

Thanks to scientific minds a process has been developed for enriching skimmed milk by emulsifying with it scientifically processed fat pressed from the white meat of the cocoanut. Thus the new food product HEBE is created to serve as an economical auxiliary to the family milk supply for cooking and baking purposes thereby reclaiming skimmed milk for human use and adding materially to the food supply of the nation.

Used in cooking and baking HEBE enriches the food and helps to balance the diet as it contains the protein, carbohydrates and mineral salts of the skimmed milk and the heat and energy units of the vegetable fat.

HEBE is produced under the most sanitary conditions—is put up in hermetically sealed cans and sterilized. The label tells plainly what HEBE is—"a compound of evaporated skimmed milk and vegetable fat" and states that it is not to be used in place of milk for infants. It is just as frankly advertised and marketed.

"HEBE—Its Dietetic and Economic Value" and "Today's Food Problem" are booklets of especial interest to physicians, health officials, dietitians, public health and industrial nurses. They will gladly be sent upon request. Address 3222 Consumers Bldg., Chicago.

Positive Results Assured

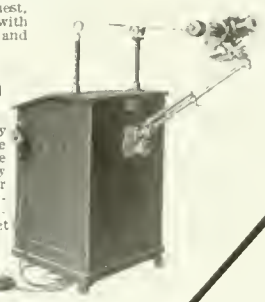
When you use

L-F Coolidge X-Ray Units

Model 530, $960

30 M. A., Variable Gap, 3 to 5"

Expressly adapted to needs of the oral surgeon, who requires films or plates of the frontal and maxillary sinuses as well as intra-oral films; or for installations where both dental and routine medical work is to be done. Fully counterbalanced tube holder. Capable of doing all radiographic work, including chest, stomach and intestinal tract. Equipped with magnetically operated exposure switch and combination cone.



Model 310, $650

10 M. A., 3" Gap

Expressly adapted to strictly dental radiography, having the advantages of the right angle Coolidge Tube. Especially easy and rapid adjustments for intra-oral work; fully counterbalanced tube holder; the complete equipment very compact and easily moved about. Can be operated either with patient in dental chair or separate chair. Operates off ordinary light wiring.

Both outfits are equipped with the L-F automatic switch, which makes possible the accurate timing of all exposures, insuring uniformity of results.

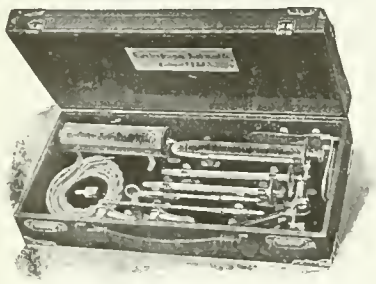
Electrically Lighted Surgical Instruments

MODERN DIAGNOSTIC OUTFIT



This outfit weighs but 4½ pounds. All Instruments can be operated by our battery with adapter or upon direct or alternating current by means of our controller.

Illustrated catalogue sent upon request.

The ever increasing demand for electrically lighted surgical instruments is the best proof obtainable of the high position to which they have advanced as diagnostic aids. Moreover, it accentuates forcibly the care to be exercised in the purchase of such instruments.

Instruments of our manufacture are constructed from the ideas and according to the suggestions of eminent physicians. We are originators of diagnostic instruments and we hold the exclusive rights to manufacture such instruments as bear the stamp "E. S. I. CO" This is our trade name, placed upon instruments for your protection.

Electro Surgical Instrument Co.

ROCHESTER, N. Y.

ECONOMIC VALUE OF MEDICINE

In a recent discussion of the work of the Baby Hygiene Association in Boston, Robert D. Curtis, M.D., medical director of the Association, declared that the greatest economic value of medicine lies in its service to infant welfare. The task of preventing sickness and keeping babies well must be carried on if the mortality rate is to be kept down. Such service should be extended so that every baby might at least be kept under observation from the time of birth to school age, when the school physician will take it in charge. The service should be extended to rich and poor alike, so that ultimately it will reach all strata of society. The work of the Society is not among sick children. The sick baby is sent to a hospital and returned to the service of the Association when it is well.

OCCUPATIONAL THERAPY ASSOCIATION ORGANIZED

The workshops at the Walter Reed Hospital, Washington, D. C., have been enlarged to promote facilities for occupational therapy for all those in need of such measures. So important has this phase of treatment become that a special organization has recently been formed by delegates which met at the Walter Reed Hospital on October 12, representing Walter Reed, Providence, Mount Alto, and St. Elizabeth's Hospitals, the Public Health Service, and the Federal Board for Vocational Education. The new Organization will be known as the District of Columbia Association of Occupational Therapy. The following officers were elected: Col. James D. Glennan, M. C., U. S. Army, honorary president; Major A. C. Monohan, Sanitary Corps, U. S. Army, president; Mrs. Helen Smith, vice-president; Miss Elsie Taft, corresponding secretary, and Miss M. Morris, treasurer.

OCCUPATION AND RACE AND HEALTH

An interesting analysis is made by G. Rome Hall, M.D., Durh., in the *Lancet* of June 5, 1920, of certain effects of occupation and race on the health of recruits. More than two million men in England, he says, have feet more or less defective who could have been cured under a State Medical Service supervising their growth. His study emphasizes the far reaching effects and the grave results of the neglect of skin hygiene. Contrary to accepted notions as to clerical occupations being unhealthy, the clerks in his series fell into surprisingly high categories. While there is absolute ill health of the Russian Jews as a whole, the close approximation of Jewish lads of eighteen born abroad, but reared in Britain, to the British standard at the same age, proves there is nothing radically wrong with the physique of the Jewish race.

Dr. Hall's analysis of 2,500 heart cases gave interesting results. Of these only 40 per cent showed excessive myocardial change. The illness of 50 per cent was due to want of tone and minor causes, nearly all quite curable if the people concerned had been in a good financial position. Many of these people will drift into invalidism and national inefficiency for want of a fair chance. Another interesting feature is the proportion of dark to fair people who figure in this cardiac list. Of the 2,500 heart cases, the proportion of dark to fair was three to two, and, since among the other recruits examined, there were two fair to every one dark, heart trouble would appear to be three times as common among the dark elements. As regards hyperthyroid action the dark are affected in the proportion of ten to one.

The Efficiency of Our Employees

Is Reflected in

The Efficiency of Our Product

Scientific apparatus represents more than a combination of material and labor. The interested, efficient, and intelligent cooperation of the workers is needed to produce efficient apparatus.

We have secured such cooperation.

We pay a bonus on production—we penalize defective workmanship.

The man who will not earn a bonus is not wanted. Every employee is an efficiency engineer.

With such support from our organization, the production of QUALITY apparatus is a natural sequence.

Let us tell you about the QUALITY in

Meyer X-Ray Transformers

Grains

Puffed to Bubbles

Food Cells Exploded

We seal whole wheat in guns and roll it for an hour in 550 degrees of heat. The trifle of moisture in each food cell is thus changed to steam.

When the guns are shot, over 100 million steam explosions occur in every kernel.

The food cells are blasted for easy digestion. The grains are puffed to bubbles, thin, flimsy and crisp, eight times normal size.

Puffed Rice is whole rice puffed in like way. Corn Puffs are corn hearts puffed.

Puffed Grains, we believe, are generally considered the ideal form of grain food. No other process so fits cereals for digestion.

Puffed Wheat
Puffed Rice
Corn Puffs

SANATORIUM FOR TUBERCULOUS SOLDIERS

The transfer of the tuberculous sanatorium hitherto operated by the Army authorities at Fort Bayard, N. M., will make available to the United States Public Health Service one thousand additional beds for the care of ambulatory cases of tuberculosis in which the prognosis is favorable. Only patients will be admitted whose condition is suitable for treatment in the climate and altitude of this sanatorium, and the patients will probably be drawn principally from the middle and southwest sections of the country.

PUBLIC HEALTH PRESERVES FAMILY TIES

A recent publication of the Metropolitan Life Insurance Company is concerned with the attempts of various governments to provide for widows and their young children in order to keep family units intact. Even with meager provisions, large expenses are being incurred by widows' pension funds and similarly organized efforts for widows and their dependent children. When mothers die and leave children with only the father to care for them, the social damage is almost as great. In such instances, some states attempt to place the child under responsible and well chosen foster mothers. But in either case where children become dependent because of the death of the father or the mother, social damage is serious; for it is in such cases that many children grow up badly and often become delinquents.

It seemed desirable, therefore, to collect data, even if in a preliminary way, to ascertain some of the facts of family damage when a married man or woman dies in wage earners' families. The facts for the families where death occurred during the months of July and August, 1920, in the industrial experience of this company were brought together. There were 663 cases in all, of which 299 represented deaths of husbands leaving surviving wives and 364 deaths of wives leaving surviving husbands. There were 1,605 living children, or an average of 2.4 per family, in all these cases. Thirty-four per cent of the children were less than sixteen years of age, and 9 per cent were under five years old. In 24 per cent of the families, there were no children at all; in 37 per cent of the families there were children under sixteen years of age and in the remainder, or 39 per cent, all the children were over sixteen years. In those cases where the parent was under forty-five at death, and leaving any children, the average number of such children under sixteen was 2.2 per family.

It is also of interest to know the causes which are responsible for the death of parents in these cases, in order to learn how to place a value on public health work as a preventive of broken families. Thus, in the 244 cases having one or more living children under sixteen years of age, tuberculosis was responsible in 65 cases for the death of the parent, or in 27 per cent, the diseases and conditions of the maternal state for 32 deaths, or in 13 per cent; organic heart disease and Bright's disease for 21 deaths each, or 9 per cent; and accidents for 19 deaths, or 8 per cent. Out of 14 accidental deaths of the father, 10 were due to work accidents. Public health work concerned with prevention of tuberculosis, of accidents and of maternal deaths has, therefore, a very important bearing upon the preservation of family ties. Public health activities should receive the support of social workers for the reason that such work helps to safeguard the family and prevents the creation of problems which social agencies must later attempt to solve.

Gonococcus Glycerol-Vaccine

Stable and Effective

Advantages:

1- Will not deteriorate. 2- Free from autolytic products.
3 – In preliminary trials has not produced toxic reactions even in large doses.

The types of cases reported to us as favorably influenced by Gonococcus Glycerol-Vaccine are chronic gonorrheal infections, including gonorrheal rheumatism, epididymitis, prostatitis and posterior urethritis.

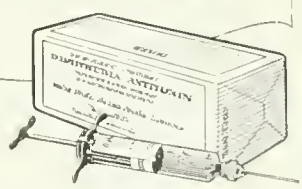
LEDERLE ANTITOXIN LABORATORIES
511 FIFTH AVENUE NEW YORK

DIPHTHERIA ANTITOXIN



Shown by Tests to Cause Least Reaction

In a series of comparative tests conducted by the John McCormick Institute for Infectious Diseases, covering 370 cases and extending over a period of 2½ years, our product—which is manufactured under the personal supervision of P. G. Heineman—gave only 3% of slight and moderate (but no severe) serum reactions.

"Since the antitoxin has been administered in a solution of almost pure globulin prepared by Heineman's method, the occurrence of serum reactions has markedly fallen, not only in frequency but also in severity." (Medical Report of the Durand Hospital of the John McCormick Institute for Infectious Diseases—March 12, 1913 to March 12, 1918.)

Our laboratories are producing this high grade concentrated serum in sufficient quantities to ensure immediate delivery of your season's requirements.

Furnished in syringes and vials containing the standard prophylactic and therapeutic doses of from 1,000 to 20,000 units.

KEEPING TAB ON SICKNESS

The relation of keeping an exact record of the incidence of sickness in industrial plants to the determination of causes of sickness and an intelligent program to eliminate preventable causes constitutes the message of a recent reprint distributed by the United States Public Health Service. The material was prepared by Dean K. Brundage, assistant statistician, and Bernard J. Newman, consulting hygienist, of the American Public Health Service. Its foreword is an argument on sound business policy involved in maintaining adequate health service in industrial plants, and the dependence of such service on a knowledge of the conditions causing ill health peculiar to each specific factory and to each particular occupation or department in the factory. In order that sickness records shall yield all pertinent information, the system of records necessary is outlined and charts suggested which will show all possible factors responsible for occupational diseases.

A comparison of results wholly in favor of the methods advocated is given in a recent report of two adjoining plants having approximately the same number of members residing in the same industrial area in which the establishment that kept such records and had a good medical department kept the incidence of influenza down to 8 per cent, while the other establishment which kept no records and had no medical department had an incidence of 25 per cent of sick employees.

TUBERCULOSIS AMONG THE INDIANS

Subdued gradually by white men from the time when Jean Nicolet first invaded their territory in 1634, the question now arises as to whether Michigan Indians will be exterminated by the great white plague of their white conquerors.

Officials of the Michigan Department of Health believe the Indians will be exterminated in time unless the state makes strenuous efforts to save them. A survey of part of the Indians in the Upper Peninsula, made during the past summer under the direction of Dr. R. M. Olin, state health commissioner, reveals that 63 per cent are either positive or suspected sufferers of tuberculosis.

One of the greatest mistakes which has been made was permitting the Indian to live off the reservations, declared Dr. Olin. While on the reservations he had some supervision. Now he has none, and, knowing absolutely nothing of preventive medicine and hygiene, he is a constant menace, spreading contagion wherever he goes. The change of the Indian's standard of living, from the healthful, vigorous life led a short time ago in the great outdoors, to his present mode of existence has been entirely too revolutionary for his physical well being. Civilization came slowly for white men; it was too abrupt for the red man.

Living as they do, housed in rude huts throughout that part of the state where the winters are most severe, the confined, inactive life that they choose is most favorable for the contact and development of tuberculosis. Even the open-air program of the summer months cannot arrest the disease for them after it is once contracted. White men often recover from tuberculosis; Indians do not take the precautions necessary to do so. The average Indian is most susceptible to other diseases and defects, due to his general weakened condition. We also found that an unusually high percentage of whites who come in contact with the Indians have contracted tuberculosis. Strict supervision on reservations is the only thing that will save the remnants of the Hurons, Ojibwas, and Chippewas in Michigan.

Nine-tenths of our physical ills are due to ignorance and perhaps a still greater proportion of our social evils are due to selfishness.—Ward.

The great reconstructive powers of VIROL

have again and again been exhibited in remarkable cases of Malnutrition, Emaciation, and Wasting, whether from Tuberculosis or other causes.

The series of *Before* and *After* photographs which we have published in this Journal during recent months afford striking illustration of the building-up properties of VIROL.

The value of VIROL in Convalescence from Fevers, Whooping Cough, and Measles, after operations, and in such conditions as Gastritis and Gastric Ulcer, has led to its use in more than 2000 Hospitals, Infirmaries, and Consumption Sanatoria in Great Britain.

VIROL has a marked effect on the metabolism of the body, increasing the production of opsonins and stimulating phagocytosis. As an adjuvant to the natural defensive processes of the patient in all diseases of bacterial origin its value can scarcely be over-estimated. It is, moreover, unequalled as a repairer of tissue waste, and is therefore of especial value in those conditions which are associated with the debilitating influences of the specific fevers.

Liberal samples of VIROL and interesting literature will be mailed to physicians on request.

Virol is composed of Red Marrow, extracted from ox rib and calves' bones by C. P. glycerine; refined Marrow and Beef Fat; highly diastasic Malt Extract; Eggs; Lemon Syrup and soluble phosphates.

IN GLASS JARS:
50c, $1.00 and $2.00

SOCIAL SERVICE SCHOOL OPENED

The Missouri School of Social Economy opened for the fall term at St. Louis, Mo., September 20. The school is conducted under the auspices of the University of Missouri, with Dr. George B. Mangold as director. The school is designed to fill the need of trained social workers.

RESEARCH IN NERVOUS DISORDERS

The first session of the Association for Research in Nervous and Mental Diseases is announced to be held in the New York Academy of Medicine, December 28 and 29. After the presidential address of Dr. Walter Timme, reports and discussions will be offered covering every phase of investigation of the subject of "lethargic encephalitis."

RESEARCH INFORMATION BUREAU

The National Research Council has established a research information service as a general clearing house and informational bureau for scientific and industrial research, service on request to be supplied concerning research problems, progress, laboratories, equipment, methods, publications, personnel, etc. Requests for information should be addressed, Research Information Service, National Research Council, 1701 Massachusetts Avenue, Washington, D. C.

FLORIDA AMBULATORY CLINICS

Plans have been announced by Dr. Ralph N. Greene, the state health commissioner of Florida of the organization of ambulatory clinics on a scale that will permit the carrying of public health service to every home in the state. The clinics will be fully equipped for eye, ear, nose and throat work, for dental diseases, and for treatment of hookworm disease. The clinics will operate from headquarters established at the county seats and will work in cooperation with the country health officers.

NEGRO INDUSTRIAL WELFARE

A program calculated to bring into a practical working unit various phases relating to the general problems of negroes in industry, their health, the housing of individual workers, and the provision of adequate and wholesome recreation, was presented at the Annual Industrial Conference of the National Urban League, Newark, N. J., October 20 to 23, 1920, in association with the negro industrial welfare workers. A discussion of wide general interest was concerned with "Health, and How Insurance Companies May Aid in Reducing Mortality." The round table conference of executives and workers included details of organization, personnel, and plans for expansion.

CARELESSNESS AND DEATH

Deaths from whooping cough and from automobile accidents, totaling 398 and 238, respectively, for the first nine months of 1920, in Michigan, are both due to the same cause, according to Dr. William J. V. Deacon, director of the bureau of communicable disease of the Michigan Department of health, and that cause, he asserts, is carelessness.

One-half of the cases of whooping cough occur among children under three years of age, Dr. Deacon declares, and the sole exciting cause is contagion. By far the greater number of children exposed to whooping cough take it. Momentary exposure is enough to transmit the infection to another person, and it is here that carelessness enters in.

CORRECTION

The notice of our readers is hereby called to the fact that the tables and charts presented in connection with the article of Dr. M. Edgar Rose on "A Personal Hygiene Demonstration," in the October issue of MODERN MEDICINE, were taken from the Annual Report of the New York State Department of Health for the year 1917.

EXTENSION CLINICS FOR PHYSICIANS

Extensions clinics open to all practising physicians in the state have been organized by the University of Michigan, the clinics to be held on the second Wednesday of each month by members of the staff of the University Hospital, Ann Arbor, including Drs. Christopher G. Parnall, Louis H. Newburgh, James G. Van Zwalenberg, and Hugh Cabot.

CALIFORNIA ON MEDICAL MEASURES

The people of the state of California strongly indorsed the position taken by the medical societies and public health organizations in the recent election, defeating the antivivisection bill, the antivaccination measures, the bill for the creation of a separate chiropractic board, and the effort of osteopaths to secure the right to prescribe drugs. This is one of the first occasions when measures pertaining strictly to medicine have been submitted to popular vote.

SPECIALISTS VISIT TUBERCULOSIS HOSPITALS

A number of eminent specialists in tuberculosis, not members of the Public Health Service, have agreed at the request of Surgeon General H. S. Cummins to visit all service hospitals and to study conditions with a view to standardization and to making such improvements as may suggest themselves. Doctors David Lyman, of Wallingfor, Conn.; Victor Cullen, of the Maryland State Sanitarium; and Martin E. Sloan, of Towson, Md., will officiate in the eastern states; Dr. George Thomas Palmer, Springfield, Ill., in the central states; and Dr. Henry Hoagland and one or more others in the southwestern states. About two weeks will be spent in each hospital.

PUBLIC HEALTH SERVICE NEEDS NURSES

The United States Public Health Service needs hundreds of graduate nurses for its general hospital work, but also and particularly for the care of former soldiers suffering from nervous and mental disorders. So great is its need for the latter class that it is probable that at present enough trained nurses are not available in the country. The Public Health Service, accordingly, purposes to establish a training school for nursing in neuropsychiatric diseases in its Special Hospital No. 49 on Grays Ferry Road, near Philadelphia, where nurses with general training may take a special course in this class of work. This hospital has a capacity of 240 patients and will afford exceptional opportunities for instruction in the most modern treatment.

An appeal is made to nurses to come forward for this work; for if they do not do so there seems to be no one to take their places. The hospitals now operated by the United States Public Health Service are already 150 nurses short; and the Service faces the necessity of opening several new ones with an inadequate force. Applications should be made to the Surgeon General, United States Public Health Service, Washington, D. C.

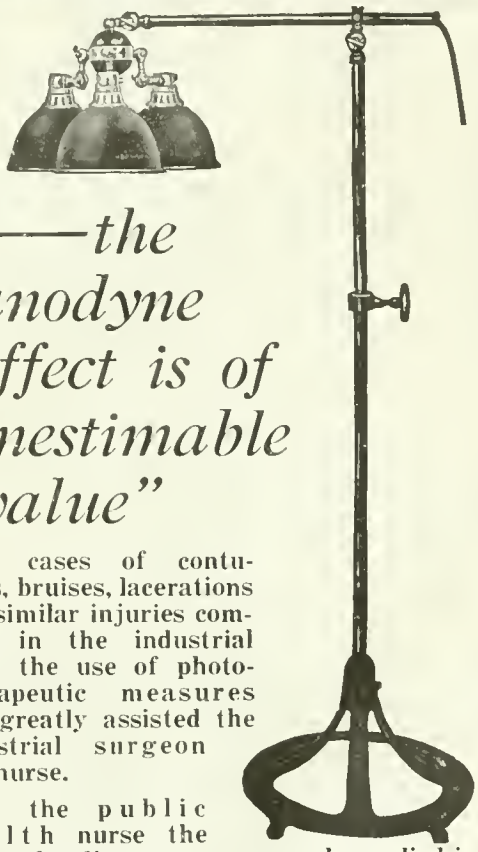
Thermolite
LIGHT AND HEAT INFUSER



"——the anodyne effect is of inestimable value"

In cases of contusions, bruises, lacerations and similar injuries common in the industrial field, the use of photo-therapeutic measures has greatly assisted the industrial surgeon and nurse.

To the public health nurse the value of radiant energy properly applied is daily apparent.

Radiant light and Heat are delivered in PARALLEL Rays for the treatment of

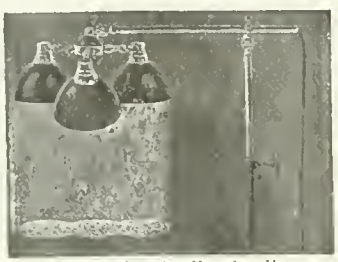
Neuralgia	Rheumatism	Chronic Ulcers
Sprains	Neuritis	Local Infections
Lumbago	Arthritis	Dsymenorrhea

and many other conditions.

Because the rays are parallel, they bring quick relief from pain, reduce inflammation, and promote healing.

ThermoLite is supplied in two forms- the **Triplex** for hospital clinics and office use, and **Simplex** (single lamp with or without stand) for home use.

H. G. McFaddin & Co.
39 Warren St., New York City



Showing **Triplex** in lineal adjustment for spinal application.

A LIVE HEALTH CRUSADE IN MILWAUKEE

Public and private agencies are cooperating in health educational work in Milwaukee. The Department of Health now supervises the health of 25,512 children in sixty-nine parochial and private schools, and 66,066 children in seventy-four public schools, according to Dr. George C. Ruhland, the City Health Officer.

Lectures on the essentials of school hygiene have been given before teachers and parents. Special health crusades have been carried on in schools and homes by the Junior Red Cross. Dietetic measures have been instituted for the undernourished; fresh air schools have been sponsored by the Wisconsin Anti-Tuberculosis Association; dental service is provided, and dispensaries give medical service when pupils are unable to have it otherwise. A substantial increase in the annual budget for health purposes enabled an increase in its staff of physicians as well as nurses for school medical inspection work.

BETTER CARE FOR SOLDIERS

A division of authority has been partly to blame for the recent criticism of the service to soldiers recently, a condition which will be remedied by the recent action of Secretary of the Treasury Houston in placing the War Risk and the Health Service under one assistant secretary.

Aside from the matters of reorganization now under way the most pressing need of the service is a marked increase in the number and efficiency of hospitals. Probably 30 per cent of the hospitals now in use should never have been utilized for hospital purposes, according to officials of the Public Health Service. These must be remedied and new hospitals erected, if proper care is to be given.

The chief difficulty has been in providing hospitals suitable for the care of the mentally deranged veterans, and for this there is no remedy until Congress can make appropriations for additional hospitals.

NEW AID FOR THE TUBERCULOUS

Promise is held out for certain patients in the South who have been treated for tuberculosis, in a report from Army medical authorities at General Hospital No. 19, at Oteen, N. C., which states that mistaken diagnosis is quite possible in the case of tuberculosis and hookworm.

The Army authorities now examine every man who enters this hospital for hookworm, and this is done irrespective of his birthplace or early geographical environment. The report says many cases which had been diagnosed as tuberculosis, on further examination showed signs of hookworm. Under treatment for hookworm, the patient regains his weight, the hemoglobin content increases, the red blood cell count goes to normal, and the color improves.

The proportion of hookworm found has been great, and the proportion of men thus afflicted, whose condition has simulated tuberculosis and yet who are non-tubercular, is said to be "startlingly large." So far as is known, this is the first medical investigation made along these lines.

Accurate figures as to the number of hookworm cases which had shown all the indications of tuberculosis will soon be compiled. It is estimated that about 10 per cent of the patients suffer from hookworm at the time of admission, and that about 2 per cent do not have tuberculosis. Even in a special field like tuberculosis a confusion of issues may arise and proof positive as to diagnosis becomes the first essential.
